Chapter 10: Asia

Coordinating Lead Authors: Rajib Shaw (Japan), Yong Luo (China), Tae Sung Cheong (Republic of Korea)

Lead Authors: Sharina Abdul Halim (Malaysia), Sanjay Chaturvedi (India), Masahiro Hashizume (Japan), Gregory E. Insarov (Russian Federation), Yoichi Ishikawa (Japan), Mostafa Jafari (Iran), Akio Kitoh (Japan), Juan Pulhin (Philippines), Chandni Singh (India), Kripa Vasant (India), Zhibin Zhang (China)

Contributing Authors: Rawshan Ara Begum (Bangladesh), Xi Chen (China), Rajarshi Dasgupta (India), Ronald C. Estoque (Philippines), Wanqin Guo (China), Garima Jain (India), Brian Johnson (USA), Tarek Katramiz (Syria), Pankaj Kumar (India), Xianbing Liu (China), Mythili Madhavan (India), Bijon Kumer Mitra (Bangladesh), Farah Mulyasari (Indonesia), Santosh Nepal (Nepal), Rekha Nianthi (Sri Lanka), Fereidoon Owfi (Iran), Gulsan Ara Parvin (Bangladesh), Shobha Poudel (Nepal), Atta-ur Rahman (Pakistan), Mihoko Sakurai (Japan), Amin Shaban (Lebanon), Dmitry Streletskiy (Russian Federation), Vibhas Sukhwani (India), Prabhakar S.V.R.K (India), Ai Tashiro (Japan), Tống Thị Mỹ Thi (Vietnam), Noralene Uy (Philippines) , Xinru Wan (China), Cunde Xiao (China)

Review Editors: Soojeong Myeong (Republic of Korea), Joy Jacqueline Pereira (Malaysia)

Chapter Scientist: Rajarshi Dasgupta (India), Yan Yang(China)

Date of Draft: 1 October 2021

Notes: TSU Compiled Version

Table of Contents

Executive Summary

Observed surface air temperature has increased in the 20th century all over Asia *(high confidence[1])*. Significant warming has intensified the threat to social and economic sustainability in Asia (*medium confidence*). Rising temperature increases likelihood of the threat of heat waves across Asia, droughts in arid and semi-arid areas of West, Central and South Asia, delays and weakening of the monsoon circulation in South Asia, floods in monsoon regions in South, Southeast and East Asia, and glacier melting in the Hindu Kush Himalaya (HKH) region (*medium confidence*). {10.3.1; 10.3.3}

Asian countries are experiencing a hotter summer climate, resulting in increase of energy demand for cooling at a rapid rate, together with the population growth *(high confidence)*. Decrease in precipitation influences energy demand as well, as desalination, underground water pumping and other energy-intensive methods are increasingly used for water supply *(high confidence)*. More energy demands in summer seasons will exceed any energy savings from relatively lower heating demand due to warmer winter. Among thirteen developing countries with large energy consumption in Asia, eleven are exposed to high energy insecurity and industrial systems risk *(high confidence)*. {10.4.1}

Asian terrestrial ecosystems change is driven by global warming, precipitation and Asian monsoon alteration, permafrost thawing and extreme events like dust storms along with natural and human-related factors which are in interplay *(high confidence)*. Treeline position in North Asian mountains moves upward after 1990s, while in Himalaya treeline demonstrates a multidirectional shift, either moves upward, or does not show upslope advance or moves downward. This can be explained by site-specific complex interaction of positive effect of warming on tree growth, drought stress, change in snow precipitation, land use change, especially grazing, and other factors *(high confidence)*. The increased considerably changes in biomes in Asia are a response to warming *(medium confidence)*. Terrestrial and freshwater species, populations, and communities alter in line with climate change across Asia *(medium-to-high confidence)*. Climate change, human activity, and lightning determine the increase of wildfire severity and area burned in North Asia after 1990s *(medium confidence)*. Length of plant growth season increased in some parts of East and North Asia, while opposite trend or no change was observed in other parts *(high confidence)*. Observed biodiversity or habitat losses of animals or plants were linked to climate change in some parts of Asia *(high confidence)*. There are evidences that climate change can alter species interaction or spatial distribution of invasive species in Asia *(high confidence)*. Changes in ecosystems in Asia during the 21st century are expected to be driven by projected climatic, natural, and socioeconomic changes. Across Asia, under a range of RCPs and other scenarios rising temperature is expected to contribute to northward shift of biome boundaries and upward shift of mountain treeline *(medium confidence)*. {10.4.2}

Coastal habitats of Asia are diverse and the impacts of climate change including rising temperature, ocean acidification and sea level rise has brought negative effects to the services and the livelihood of people depending on it *(high confidence)*. The degree of bleaching of coral reefs was diverse among different presences of stress tolerant symbionts and higher thermal thresholds. The risk of irreversible loss of coral reefs, tidal marshes, seagrass meadows, plankton community and other marine and coastal ecosystems increases with global warming, especially at 2°C temperature rise or more *(high confidence)*. Mangroves in the region continue to face threats due to pollution, conversion for aquaculture, agriculture, in addition to climate based threats like SLR (Sea Level Rise) and coastal erosion. {10.4.3}

Both climatic and non-climatic drivers such as socio-economic changes have created water stress conditions in both water supply and demand in all sub-regions of Asia *(high confidence)*. These changes in space and time directly or indirectly affected water use sectors and services. By mid-21st Century, the international transboundary river basins of Amu Darya, Indus, Ganges and inter-state Sabarmati river basin in India could face severe water scarcity challenges with climate change acting as a stress multiplier *(high confidence)*. Due to global warming Asian countries could experience increase of drought conditions (5-20%) by the end of this century *(high confidence)*. {10.4.4}

[1] In this Report, the following summary terms are used to describe the available evidence: limited, medium, or robust; and for the degree of agreement: low, medium, or high. A level of confidence is expressed using five qualifiers: very low, low, medium, high, and very high, and typeset in italics, e.g., *medium confidence*. For a given evidence and agreement statement, different confidence levels can be assigned, but increasing levels of evidence and degrees of agreement are correlated with increasing confidence.

The Asia glaciers are in minor area shrinkage and mass loss during 2006-2016, resulting in the instability of water resource supply *(high confidence)*. Glaciers in Asia are the water resources of about 220 million people in the downstream areas. The glacier meltwater in southern Tibetan Plateau has increased during 1998-2007, and will further increase till 2050. The glacier is *likely*[2] to disappear by nearly 50% in High Mountain Asia and about 70% in Central and Western Asia by the end of the 21st century under the medium scenario, and more under the high scenario. The total amount and area of glacier lakes were found increased during last decade *(high confidence)*. More glacier collapses and surges were found in western Tibet. Glacier lake outburst flood (GLOF) will threaten the securities of the local and downstream communities *(high confidence)*. Snowmelt water contributed 19% of the increase change in runoff of arid region's rivers in Xinjiang, China and 10.6% of the upper Brahmaputra River during 2003-2014 *(medium confidence)*. {10.4.4; Box 10.5}

Since IPCC AR5, more studies reinforce the earlier findings on the spatial and temporal diversity of climate change impacts on food production in Asia depending on the geographic location, agro ecology, and crops grown, recognizing that there are winners and losers associated with the changing climate across scales *(high confidence)*. Most of these impacts have been associated with drought, monsoon rain, and oceanic oscillations, the frequency and severity of which have been linked with the changing climate. Climate-related risks to agriculture and food systems in Asia will progressively escalate with the changing climate, with differentiated impacts across the region *(medium confidence)*. Major projected impacts of climate change in the agriculture and food sector include decline in fisheries, aquaculture, and crop production particularly in South and Southeast Asia, reduction in livestock production in Mongolia, and changes in crop, farming systems and crop areas in almost all regions with negative implications to food security *(medium confidence)*. In India, rice production can decrease from 10% to 30% whereas maize production can decrease from 25% to 70% assuming a range of temperature increase from 1º to 4°C. Similarly, rice production in Cambodia can decrease by 45% by 2080 under high emission scenario. Occurrence of pests such as the golden apple snail (Pomacea canaliculate), associated with the predicted increase in climatically suitable habitats in 2080, threatens the top Asian rice-producing countries including China, India, Indonesia, Bangladesh, Vietnam, Thailand, Myanmar, Philippines and Japan. Increasing temperatures, changing precipitation levels, and extreme climate events like heat waves, droughts and typhoons will persist to be important vulnerability drivers that will shape agricultural productivity particularly in South Asia, Southeast Asia, and Central Asia. {10.4.5; Figure 10.6}

Asian urban areas are considered high risk locations from projected climate, extreme events, unplanned urbanisation, rapid land use change *(high confidence)* but also sites of ongoing adaptation *(medium confidence)*. Asia is home to the largest share of people living in informal settlements, with 332 million in Eastern and South-Eastern Asia, 197 million in Central and Southern Asia. By 2050, 64% of Asia's population will be urban. Coastal cities, especially in South and South East Asia are expected to see significant increase in average annual economic losses between 2005 and 2050 due to flooding, with very high losses in East Asian cities under high emission scenario *(high confidence)*. Climate change will amplify the urban heat island effect across Asian cities (especially South and East Asia) at 1.5°C and 2°C temperature rise, both substantially larger than under the present climate *(medium evidence, high agreement)*. Under high emission scenario, higher risks from extreme temperature and precipitation are projected for almost all cities *(medium confidence)*, with impacts on freshwater availability, regional food security, human health, and industrial outputs. By 2080, 940-1100 million urban dwellers in South and South East Asia could be affected by extreme heat lasting more than 30 days/year *(high confidence)*, with poorer populations affected the most. {10.4.6; Cross-Chapter Box URBAN in Chapter 6}

Climate change caused direct losses due to the damage in infrastructure, disruption in services and affected supply chains in Asia *(medium confidence)* and will increase risk to infrastructure as well as provide opportunities to invest in climate-resilient infrastructure and green jobs *(medium confidence)*.

[2] In this Report, the following terms have been used to indicate the assessed likelihood of an outcome or a result: Virtually certain 99–100% probability, Very likely 90–100%, Likely 66–100%, About as likely as not 33–66%, Unlikely 0–33%, Very unlikely 0–10%, and Exceptionally unlikely 0–1%. Additional terms (Extremely likely: 95–100%, More likely than not >50–100%, and Extremely unlikely 0–5%) may also be used when appropriate. Assessed likelihood is typeset in italics, e.g., *very likely*. This Report also uses the term 'likely range' to indicate that the assessed likelihood of an outcome lies within the 17-83% probability range.

At higher warming, key infrastructures such as power lines, transport by roads, railways, and built infrastructure such as airports and harbours are more exposed to climate-induced extreme events, especially in coastal cities *(medium confidence)*. Evidence on urban adaptation across Asia is growing with examples on infrastructural adaptation (e.g. flood protection measures, and climate resilient highways and power infrastructure); institutional adaptation (e.g. sustainable land use planning, zoning plans); nature ecosystem-based solutions (e.g. mangrove restoration, restoring and managing urban green spaces, urban farming); technological solutions (e.g. smart cities, early warning systems); and behavioural adaptation (e.g. improved awareness and preparedness measures). However, adaptation actions tend to be in initial stages and more reactive (57% urban adaptations focus on preparatory interventions such as capacity building and 43% cities report implemented adaptation interventions) *(medium confidence)*. The degree of implementation of urban adaptation is uneven with large cities receiving more funding and priority and smaller cities and towns and peri-urban spaces seeing relatively lower adaptation action *(medium confidence)*. {10.4.6}

Climate change is increasing vector-borne and water-borne diseases, undernutrition, mental disorders and allergic diseases in Asia by increasing the hazards such as heatwaves, flooding and drought, air pollutants, in combination with more exposure and vulnerability *(high confidence)*. Sub-regional diversity in socioeconomic and demographic context (e.g., ageing, urban vs agrarian society, increasing population vs reduced birth rate, high income vs low to middle income) and geographical characteristics largely define the differential vulnerabilities and impacts within countries in Asia. Under the medium-high emissions scenario, rising temperature and extreme climate events will have an increasing impact on human health and wellbeing with varying types and magnitudes of impact across Asia *(high confidence)*. More frequent hot days and intense heat-waves will increase heat-related deaths in Asia. Increased floods and droughts will have adverse impact on food availability and prices of food resulting in increased undernourishment in South and Southeast Asia. Increases in heavy rain and temperature will increase the risk of diarrheal diseases, dengue fever and malaria in tropical and sub-tropical Asia. {10.4.7}

Increased climate variability and extreme events are already driving migration *(robust evidence, medium agreement)* and projecting longer-term climate change will increase migration flows across Asia *(medium confidence)*. One in three migrants comes from Asia and the highest ratio of outward migrants is seen from hazard-exposed Pacific countries. In 2019, Bangladesh, China, India and the Philippines each recorded more than 4 million disaster displacements. In South East and East Asia, cyclones, floods, and typhoons triggered internal displacement of 9.6 million people in 2019, almost 30% of total global displacements. {Box 10.2}

There is a small but growing literature highlighting the importance of behavioural aspects of adaptation in Asia *(high confidence)* but this is restricted primarily in agriculture and disaster risk reduction. Factors motivating adaptation actions include risk perception, perceived self-efficacy, socio-cultural norms and beliefs, previous experiences of impacts, levels of education and awareness *(high confidence)*. There is growing evidence on behavioural aspects of individual adaptation but lesser evidence on the socio-cognitive factors motivating governments and private sector actors to adapt. {10.5.3}

Climate change is already causing economic loss and damage across Asian regions and this will increase under higher warming *(medium confidence)*. Non-material losses and damages are reported to a lesser degree but this is due to underreporting and methodological issues with detection and attribution to climate change (*high confidence*). Loss and damage represents a key knowledge gap, especially in West, Central and North Asia. Insufficient literature differentiating loss and damage under future adaptation scenarios restricts a comprehensive assessment of residual damages and future loss and damage difficult. {Box 10.7}

Options such as climate smart agriculture, ecosystem-based disaster risk reduction, investing in urban blue-green infrastructure meet adaptation, mitigation, and sustainable development goals simultaneously, presenting opportunities for climate-resilient development (CRD) pathways in Asia *(high confidence)*. Climate risks, vulnerability and adaptation measures need to be factored into decision-making across all levels of governance (*high confidence*). To help achieve this, there is a need to advance the current understanding of climate impacts across sectors and spatiotemporal scales and improve on the current strategies in planning and budget allocation. More accurate forecasting of extreme events, risk awareness and prioritizing individual and collective decision choices are also need to be enhanced *(high confidence)*.

Options for Asian countries are transforming risks of climate change into opportunities for the advancement of projects in the energy sector – including promoting investment in non-fossil energies, securing local natural gas resources, enhancing water harvesting, adopting green building technologies, and encouraging multi-stakeholder partnerships. However, there are significant barriers to CRD such as fragmented, reactive governance; inadequate evidence on which actions to prioritise and how to sequence them; and finance deficits. Some Asia countries and regions offer solutions to overcome these barriers: Through use of advanced technologies (in-situ observation and remote sensing, a variety of new sensor technologies, citizen science, artificial intelligence, and machine learning tools); regional partnerships and learning; improved forecasting capabilities; and better risk awareness (*high confidence*). {10.5, 10.6}

10.1 Introduction

Asia is defined here as the land and territories of 51 countries/regions (**Figure 10.1**). It can be broadly divided into six sub-regions based on geographical position and coastal peripheries (IPCC, 2014b). These are, in alphabetical order, Central Asia (five countries), East Asia (seven countries/regions), North Asia (two countries), South Asia (eight countries), Southeast Asia (12 countries), and West Asia (17 countries). The population of Asia was reported to be about 4463 million in 2016, which is about 60% of the world population with an estimated density of 100 people per square kilometer (UNDESA, 2017). The highest life expectancy at birth is 84 (Japan) and the lowest is 52 (Afghanistan) (CIA, 2017). The gross domestic product (GDP) per capita ranged from US$587 (Afghanistan) to US$81,585 (Macao, PRC) (IMF, 2018).

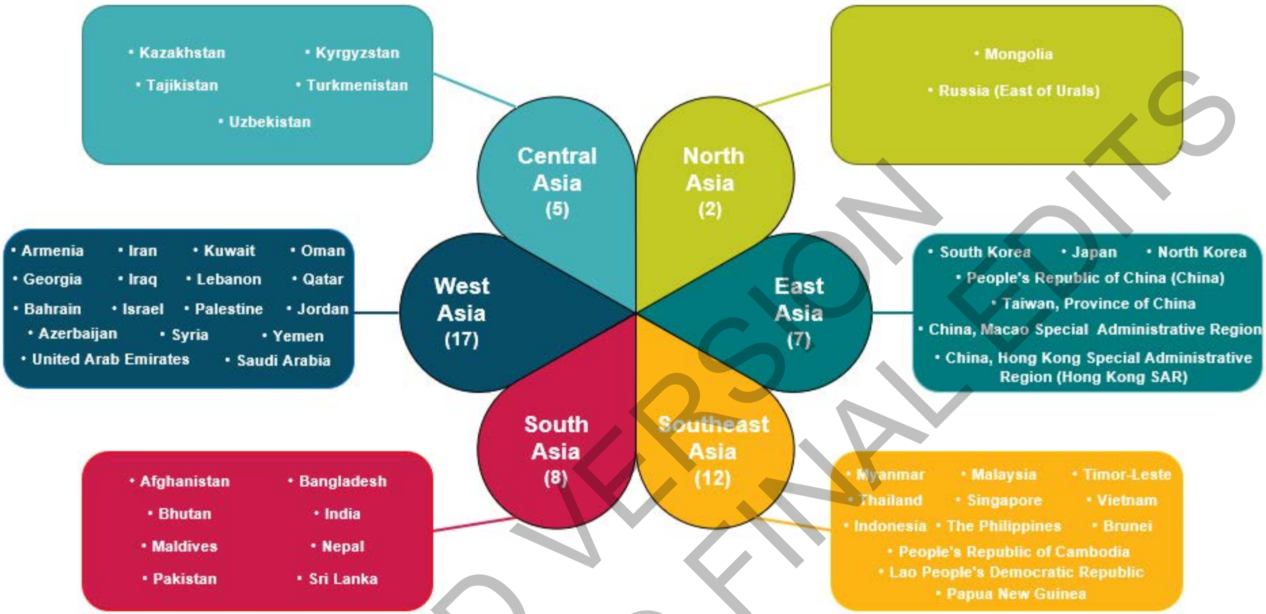

Figure 10.1: Countries and regions in Asia

[START BOX 10.1 HERE]

Box 10.1: What is New on Asia in AR6?

- Adaptation in energy sector is becoming increasingly crucial in the Asian region, which has been assessed in a new sub-section.
- Adaptation technology and innovations are also of high importance for the region. Classification of adaptation technology and its use in different systems are assessed.
- On the governance side, the nexus approach among several systems like food, energy, water is focused, and its importance is assessed.
- New concepts on decentralised and self-reliant society, such as the Circulating and Ecological Sphere (CES) are emerging for integrated adaptive governance.
- As a part of sustainable development pathway, interlinkages of climate change adaptation and disaster risk reduction is highlighted.

[END BOX 10.1 HERE]

10.2 Major Conclusions from Previous Assessments

As the most populous continent, Asia is faced with a unique set of challenges that vary across its climatic zones.

- The most perceptible change in climatic trends is observable in the increasing surface air temperature and rise in night time temperature, particularly during the season of winter. This is accompanied by monsoon rainfall variability, which is observable inter-seasonally, inter-annually and spatially.
- There is increasing evidence of an upward trend in the intensity and frequency of extreme weather events in Asia.
- The predictions for future climatic trends suggest an increase in warming along the higher latitudes of North Asia.
- Projections show that agricultural and food security will be impacted substantially, particularly in the area of cereal production by the end of the 21st century.
- Malnutrition among the poor and marginalised sections of the population in Asia remains a major concern that is further rendered complex by climate change.
- Projections of an increase in the incidence of pests and diseases impacts directly on the food security and health of vulnerable populations.
- Erosion will occur simultaneously with sea level rise; the projected rise could lead to large-scale flooding in low-lying areas, particularly South, Southeast and East Asia.
- The erosion of the major deltas of Asia may take place through a rise in sea levels, an increased frequency of extreme weather events, and the excessive withdrawal of groundwater.
- The priority areas for Asia include an enhancement of capabilities to collect social and biophysical data, information sharing, sectoral interactions, a mainstreaming of science and the identification of critical climate thresholds across regions and sectors.

Drawing upon a greater number of studies made possible by greater use of advanced research tools such as remote sensing as well as meticulous modelling of impacts, the Fifth Assessment Report could significantly expand its coverage of pertinent issues (IPCC, 2014c). For example, the discussion on the Himalayas was expanded to cover observed and projected impacts of climate change on tourism (see WGII AR5 Section 10.6.2); livelihood assets such as water and food (WGII AR5 Sections 9.3.3.1, 13.3.1.1, 18.5.3, 19.6.3); poverty (WGII AR5 Section 13.3.2.3); culture (WGII AR5 Section 12.3.2); flood risks (WGII AR5 Sections 18.3.1.1, 24.2.1); health risks (WGII AR5 Section 24.4.6.2); and ecosystems (WGII AR5 Section 24.4.2.2)(IPCC, 2014c).

- Over the past century, and across most of Asia, warming trends and increasing temperature extremes have been observed.
- Adequate supplies of freshwater resources are under considerable threat due to both the existing pattern of socio-economic growth and climate change.
- With a number of regions already close to the heat stress limits, most models, using a range of General Circulation Models (GCMs) and Special Report on Emission Scenarios (SRES) scenarios, suggest that higher temperatures will lead to shorter growing periods of rice cultivation resulting in lower rice yields.
- Climate change impacts have led to visible shifts on the terrestrial systems in many parts of Asia in the phenologies, growth rates, and the distributions of plant species.
- Coastal and marine systems in Asia are under increasing stress from both climatic and non-climatic drivers and mean sea level rise will contribute to upward trends in extreme coastal high water levels (WGI AR5 Section 3.7.6).(IPCC, 2014c) . Mangroves, salt marshes, and seagrass beds may decline unless they can move inland, while coastal freshwater swamps and marshes will be vulnerable to saltwater intrusion with rising sea levels. Damage to coral reefs will increase during the 21st century because of both warming and ocean acidification.
- Climate change will further compound multiple stresses caused due to rapid urbanisation, industrialisation, and economic growth. Development of sustainable cities in Asia with fewer fossil fuel-driven vehicles and with more trees and greenery would have a number of co-benefits, including improved public health.
- Extreme climate events will have an increasing impact on human health, security, livelihoods, and poverty, with the type and magnitude of impact varying across Asia.
- Local Knowledge and Indigenous Knowledge play an important role in the formulation of adaptation governance and related strategies (IPCC, 2007), and best quality, locality specific knowledge can help address serious lack of education on climate change and uncertainties surrounding quality, salience, credibility and legitimacy of available knowledge base.

Knowledge/research gaps identified in AR5 include, but are not limited to, an insufficient understanding of impacts, vulnerability and adaptation in urban settlements, under-researched linkages between local livelihoods, ecosystem functions, and land resources and a poor understanding of the impacts of projected climate changes on the vegetation of the lowland tropics.

10.3 Regional and Sub-regional Characteristics

10.3.1 Climatic Characteristics

Climate characteristics in Asia is diverse covering all climate zones from tropical to polar climate, including mountain climate. Monsoonal winds and associated precipitation are dominant in South, Southeast and East Asia. Annual mean surface air temperature averaged over the sub-region ranges from coldest North Asia (–3°C) to warmest Southeast Asia (25°C) based on JRA-55 (Kobayashi et al., 2015) climatology for 1981–2010. Most of North Asia and higher altitude is underlain by permafrost. West Asia is the driest and Southeast Asia is the wettest, with the annual precipitation averaged over the sub-region ranging about 10 times from 220 mm in West Asia to 2570 mm in Southeast Asia based on GPCC (Schamm et al., 2014) climatology for 1981–2010. Indonesia in Southeast Asia has the longest coastline in the world, causing this area (maritime continent) the wettest region (Yamanaka et al., 2018). The Hindu Kush-Himalaya (HKH) region is a biodiversity hotspot (Wester et al., 2019), and also has significant impacts on the Asian climate because of their orographic and thermodynamic effects (Wu et al., 2012).

Extreme precipitation events and related flooding occur frequently in monsoon Asia, i.e., Southeast, South and East Asia (Mori et al., 2021b). Tropical cyclones also affect East and South Asia with torrential rain, strong winds and storm surge. Floods and other weather-related hazards are causing thousands of casualty and millions of affected people each year (CRED/UNISDR, 2019). On the other hand, droughts have long-lasting effects on agriculture and livestock threatening water security in West Asia, Central Asia and northern China (Ranasinghe et al., 2021; Seneviratne et al., 2021). Adaptation to such extreme events was limited in Asia.

10.3.1.1 Observed climate change

Observations of past and current climate in Asia are assessed in IPCC WGI AR6 (IPCC, 2021a). Examples of observed impacts in Asia with attributed climatic impact-drivers (CIDs) are shown in **Figure 10.2.** Surface temperature has increased in the past century all over Asia (*very high confidence*). Elevation dependent warming, i.e. that the warming rate is different across elevation bands, is observed in high mountain Asia (*medium confidence*) (Krishnan et al., 2019) (Hock et al., 2019). While there is an overall trend of decreasing glacier mass in high mountain Asia, there are some regional differences and even areas with a positive mass balance due to increased precipitation (Wester et al., 2019). Rising temperature resulted in an increasing trend of growing season length. Number of hot days and warm nights continue to increase in the whole Asia (*high confidence*), while cold days and nights decrease except in the southern part of Siberia (Gutiérrez et al., 2021). Large increases in temperature extremes are observed in West and Central Asia (*high confidence*). Temperature increase is causing strong, more frequent, and longer heat waves in South and East Asia. East China 2013 heat waves case is such an example (Xia et al., 2016). Extreme warmth was observed in Asia in 2016 and 2018, for which event attribution study revealed that this would not have been possible without anthropogenic global warming (*medium confidence*) (Imada et al., 2018; Imada et al., 2019).

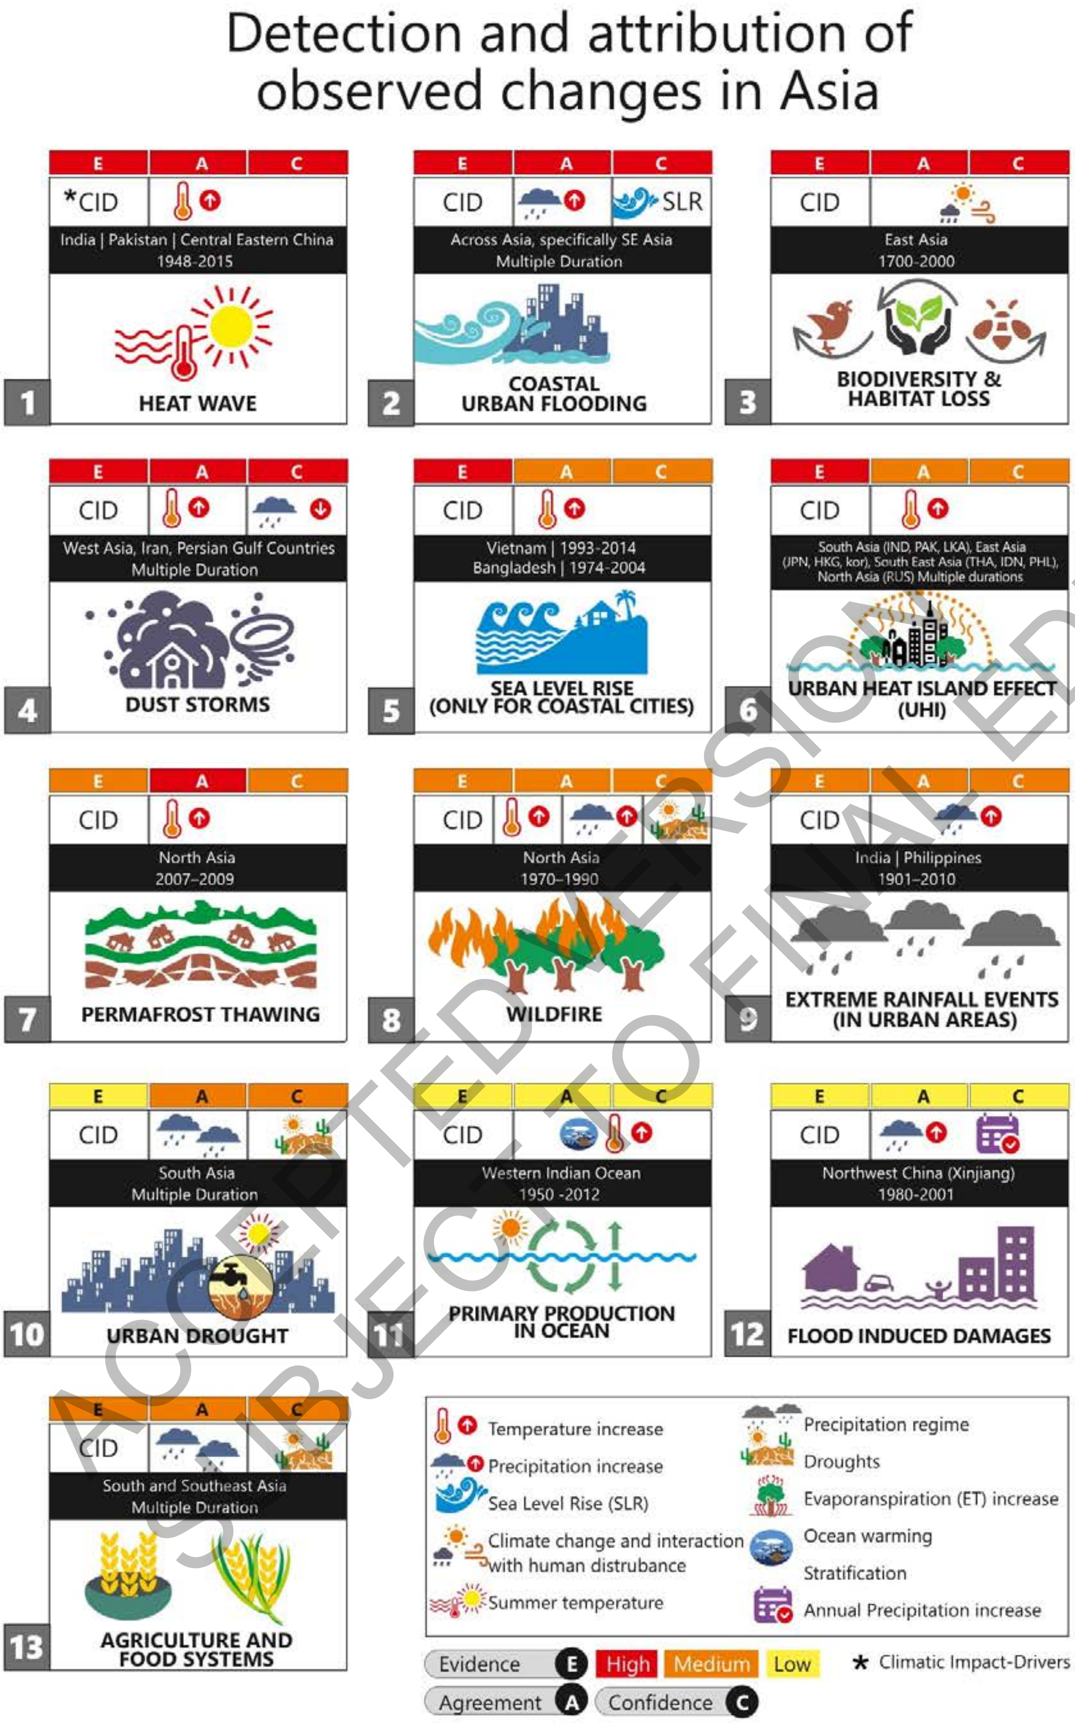

Figure 10.2: Detection and attribution of observed changes in Asia; Levels of Evidence (E), Agreement (A) and Confidence (C) are ranked by High (H), Medium (M) or Low (L). CID: Climatic Impact-Driver. References: (1) Heat waves, (Ross et al., 2018); (Mishra et al., 2015); (Rohini et al., 2016); (Panda et al., 2017); (Chen and Li, 2017). (2) Coastal urban flooding, (Dulal, 2019). (3) Biodiversity & habitat loss, (Wan et al., 2019). (4) Dust storms, (Alizadeh-Choobari et al., 2016); (Nabavi et al., 2016); (Yu et al., 2015); (Kelley et al., 2015). (5) Sea level rise (only for coastal cities),(Hens et al., 2018) (Brammer, 2014); (Shahid et al., 2016). (6) Urban heat island effect (UHI), (Kotharkar et al., 2018); (Choi et al.,

2014); (Estoque et al., 2017); (Santamouris, 2015); (Li et al., 2018a); (Ranagalage et al., 2017); (Hong et al., 2019c). (7) Permafrost thawing, (Biskaborn et al., 2019); (Shiklomanov et al., 2017a). (8) Wildfire, (Brazhnik et al., 2017); (Schaphoff et al., 2016). (9) Extreme rainfall events (in urban areas), (Ali et al., 2014). (10) Urban drought, (Pervin et al., 2020), (Gu et al., 2015). (11) Primary production in ocean, (Roxy et al., 2016). (12) Flood induced damages, (Fengqing et al., 2005). (13) Agriculture and food systems(Heino et al., 2018) (Prabnakorn et al., 2018)

There are considerable regional differences in observed annual precipitation trend (*medium confidence*). Observations show a decreasing trend of the South Asian summer monsoon precipitation during the second half of the 20th century (*high confidence*) (Douville et al., 2021). No clear trend in precipitation is observed in high mountain Asia (Nepal and Shrestha, 2015), while continuous shift toward a drier condition was observed since early 1980s in spring over the central Himalaya (Panthi et al., 2017). Increase in heavy precipitation occurred recently in South Asia (*high confidence*), and in Southeast and East Asia (*medium confidence*) (Seneviratne et al., 2021). In Japan, there is no significant long-term trend in the annual precipitation, while significant increasing trend is observed in the annual number of events of heavy precipitation (daily precipitation ≥ 400 mm) and intense precipitation (hourly precipitation ≥ 50 mm) (JMA, 2018). Decreased precipitation and increased evapotranspiration are observed in West and Central Asia, contributing to drought conditions and decreased surface runoff.

Annual surface wind speeds are decreasing in Asia since 1950s (*high confidence*) (Ranasinghe et al., 2021). The observed changes in the frequency of sand and dust storms vary from region to region in Asia (*medium confidence)*. The frequency and intensity of dust storms are increasing in some regions of Asia, such as West and Central Asia, due to land use and climate change (Mirzabaev et al., 2019). Significant decreasing trends of dust storms are observed in some part of Inner Mongolia and over the Tibetan Plateau (Ranasinghe et al., 2021). In contrast, West Asia has witnessed more frequent and intensified dust storms affecting Iran and Persian Gulf countries in the past decades (*medium confidence*) (Nabavi et al., 2016).

There is no significant long-term trend during 1951–2017 in the numbers of tropical cyclones (TCs) with maximum winds of 34 kt or higher forming in the western North Pacific and the South China Sea (*medium confidence*). There are substantial interdecadal variations in basin-wide TC frequency and intensity in the western North Pacific (Lee et al., 2020a). Numbers of strong TCs (maximum winds of 64 kt or higher) also show no discernible trend since 1977 when complete wind speed data near TC center becomes available (JMA, 2018). For TCs in the Philippines area, there are no significant trends in the annual number of TCs during 1951–2013 (Cinco et al., 2016). Their analysis showed that the Philippines have been affected by fewer TCs above 64 kt, but affected more by extreme TCs (above 81 kt). There is a significant northwestward shift in TC tracks since the 1980s, and a detectable poleward shift since the 1940s in the average latitude where TCs reach their peak intensity in the western North Pacific (Lee et al., 2020a) (*medium confidence*).

The oceans have warmed unabated since 2004, continuing the multi-decadal ocean warming trends (Bindoff et al., 2019). The report also summarised that there is increased agreement between coupled model simulations of anthropogenic climate change and observations of changes in ocean heat content (*high confidence*). Observed sea level rise around Asia over 1900–2018 is similar to the global mean sea level change of 1.7 mm/yr, but for the period 1993–2018, the sea level rise rate increased to 3.65 mm/yr in the Indo-Pacific region and 3.53 m/yr in the Northwest Pacific, compared to global value of 3.25 mm/yr (Ranasinghe et al., 2021). The extreme sea level has risen since 1980s along the coast of China (Feng et al., 2018b).

Ocean acidification continues with surface seawater pH values have shown a clear decrease by 0.01–0.09 from 1981–2011 along the Pacific coasts of Asia (*high confidence*) (Lauvset et al., 2015). For the western north Pacific along the 137°E line, the trend varies from –0.013 at 3°N to –0.021 at 30°N per decade during 1985–2017 (JMA, 2018). Ocean interior (about 150–800 m) pH also shows a decreasing trend with higher rates in the northern than the southern subtropics, which may be due to greater loading of atmospheric CO_2 in the former (JMA, 2018).

10.3.1.2 Projected climate change

Rising temperature increases likelihood of the threat of heat waves across Asia, droughts in arid and semi-arid areas of West, Central and South Asia, floods in monsoon regions in South, Southeast and East Asia, and glacier melting in the HKH region (*high confidence*) (Doblas-Reyes et al., 2021; Ranasinghe et al., 2021; Seneviratne et al., 2021). Confidence in direction of projected change in climatic impact-drivers in Asia are summarised in Table 12.4 of WGI AR6 Chapter 12 (Ranasinghe et al., 2021).

Projections of future annual mean surface air temperature change in Asia are qualitatively similar to those in the previous assessments with larger warming in higher latitudes, i.e. North Asia (*high confidence*) (Gutiérrez et al., 2021). Projected surface air temperature changes in the Tibetan Plateau, Central Asia and West Asia are also large (*high confidence*) (Gutiérrez et al., 2021). Highest levels of warming for extreme hot days are expected to occur in West and Central Asia with increased dryness of land (*high confidence*) (SR1.5). Over mountainous regions, elevation dependent warming will continue (*medium confidence*) (Hock et al., 2019). Glacier will generally shrink, but rates vary among region to region (*high confidence*) (Wester et al., 2019). Thawing permafrost presents a problem in northern areas of Asia, particularly Siberia (Parazoo et al., 2018). Temperature rise will be strongest in winter in most regions, while it will be strongest in summer in the northern part of West Asia and some parts of South Asia where desert climate prevails (*high confidence*) (Gutiérrez et al., 2021). The wet-bulb globe temperature (WBGT), which is a measure of heat stress, is *likely* to approach critical health thresholds in West and South Asia under the RCP4.5 scenario, and in some other regions such as East Asia under the RCP8.5 scenario (*high confidence*) (Lee et al., 2021a) (Seneviratne et al., 2021). Occurrence of extreme heat waves *very likely* increases in Asia. Projections show that a sizeable part of South Asia will experience heat stress conditions in the future (*high confidence*). It is *virtually certain* that cold days and nights become fewer (Ranasinghe et al., 2021).

Projections of future annual precipitation change are qualitatively similar to those in the previous SREX and AR5 assessments (IPCC, 2021a). *Very likely* large percent increase in annual precipitation is projected in South Asia and North Asia (*high confidence*) (Lee et al., 2021a) (Douville et al., 2021). Precipitation is projected to decrease over the north-western part of the Arabian Peninsula and increase over its southern part (*medium confidence*) (Gutiérrez et al., 2021). Both heavy precipitation and intense precipitation are projected to intensify and become more frequent in South, Southeast and East Asia (*high confidence*) (Seneviratne et al., 2021). There will be a large increase in flood frequency in these monsoon regions (Oppenheimer et al., 2019). This would lead to continuation to cause loss of lives and infrastructure without further mitigation efforts. SR1.5 assessed higher risk from heavy precipitation events at 2°C compared to 1.5°C of global warming in East Asia. A large ensemble modelling study shows that future warming is expected to further increase winter precipitation and extreme weather events such as rain-on-snow, result in the increase in extreme runoff in Japan (*low confidence*) (Ohba and Kawase, 2020). The earlier snowmelt will affect energy supply by hydropower.

Monsoon land precipitation *likely* increases in East, Southeast, and South Asia mainly due to increasing moisture convergence by elevated temperature (*high confidence*). However, there is *low confidence* in the magnitude and detailed spatial patterns of precipitation changes at sub-regional scale in East Asia (Doblas-Reyes et al., 2021). Increasing land-sea thermal contrast and resultant lower tropospheric circulation changes, together with increasing moisture, are considered to intensify the South Asian summer monsoon precipitation (*medium confidence*). Anthropogenic aerosols greatly modify sub-regional precipitation changes and their spatial and temporal changes are uncertain (Douville et al., 2021). Monsoonal winds will generally become weaker in future warming world with different magnitude across regions (*medium confidence*). Future changes in sand and dust storms are uncertain.

The global proportion of very intense TCs (category 4-5) will increase under higher levels of global warming (*medium-to-high confidence*). Mean global TC precipitation rate will increase (*medium-to-high confidence*). Models suggest a reduction of TC frequency, but an increase in the proportion of very intense TCs over the western North Pacific in the future. However, some individual studies project an increase in western North Pacific TC frequency (*medium confidence*) (Cha et al., 2020). In the western North Pacific, some models project a poleward expansion of the latitude of maximum TC intensity, leading to a future increase of intense TC frequency south of Japan (*medium confidence*) (Yoshida et al., 2017).

Relative sea level rise associated with climate change in Asia will range from 0.3 m–0.5 m in SSP1-2.6 to 0.7 m–0.8 m in SSP5-8.5 for 2081–2100 relative to 1995–2014 (Ranasinghe et al., 2021). In coastal region, evaluation of sea level rise is necessary in regional scale to assess the impacts on coastal sector. Liu et al. (2016c) investigates the regional scale sea level rise using dynamical downscaling from the three global climate models in western North Pacific. In their projection in the case following RCP 8.5 scenario, the regional sea level rises along Honshu Island in Japan during 2081–2100 relative to 1981–2000 are 6–25 cm higher than the global mean sea level rise due to the dynamical response of the ocean circulation. For the impact assessment of coastal hazard, the total sea level rise including extreme events due to the storm surge and high ocean wave, which are influenced by the changes of TCs (Seneviratne et al., 2021). Mori and Takemi (2016) summarised the characteristics of TCs in the western Pacific in the past and in the future, and the extreme value of significant wave height increase in several regions. There is considerable increase of the return levels along the China coast under 2.0°C warming compared with that under 1.5°C warming scenario (Feng et al., 2018b).

Ocean acidification will continue over the 21st century (*virtually certain*) (SROCC). Projected decrease in global surface ocean pH from 1986–2005 to 2081–2100 is about 0.145 under RCP4.5 (Lee et al., 2021a).

Diverse and complex climatic characteristics in Asia make the climate models' ability limited in reasonably simulating the current climate and projecting its future change (Gutiérrez et al., 2021).

10.3.2 Ecological Characteristics

Ecosystems in Asia are characterised by a variety of climate and topographic effects and can be divided into several distinct areas (Figure 10.3), and valuable ecosystem services provide vital support for human well-being and sustainable development (IPBES, 2018).

Boreal forests and tundra dominate in North Asia, deserts and xeric shrub-lands in Central and West Asia, and alpine ecosystems in the Hindu Kush-Himalaya, Tian Shan, Altai-Sayan, Ural and Caucasus mountain regions. Human-transformed landscapes occupies most parts of other sub-regions. Remained natural ecosystems in East Asia are temperate broadleaf and mixed forests and subtropical evergreen forests, and deserts and grasslands in the west. South Asia has tropical forests and semi-deserts in the northwest. Southeast Asia is covered mainly by tropical forests (Figure 10.3).

Ocean and coastal region in Asia have various ecological characteristics, such as high productivity in arctic/subpolar region, large biodiversity in tropical region, and unique system in marginal seas. In the atlas of WGI AR6, the ocean biomes in Asia is divided into 6 sub-regions (WGI AR6 Figure Atlas.4) (Gutiérrez et al., 2021). For the coastal region, the concept of the large marine ecosystem (e.g., (Sherman, 1994) provides the biological characteristics each marginal/semi-enclosed region and the regions characterised by boundary current system.

Biodiversity and ecosystem services play a critical role in socioeconomic development as well as the cultural and spiritual fulfilment of the population in the Asia (IPBES, 2018). For example, species richness reaches it maximum in the "coral triangle" of South-East Asia (central Philippines and central Indonesia) (IPCA, 2017) and the extent of mangrove forests in Asia is about 38.7% of the global total (Bunting et al., 2018). These coastal ecosystems provide multiple ecosystem services related to food production by fisheries/aquaculture, carbon sequestration, coastal protection, and tourism/Recreation (Ruckelshaus et al., 2013).

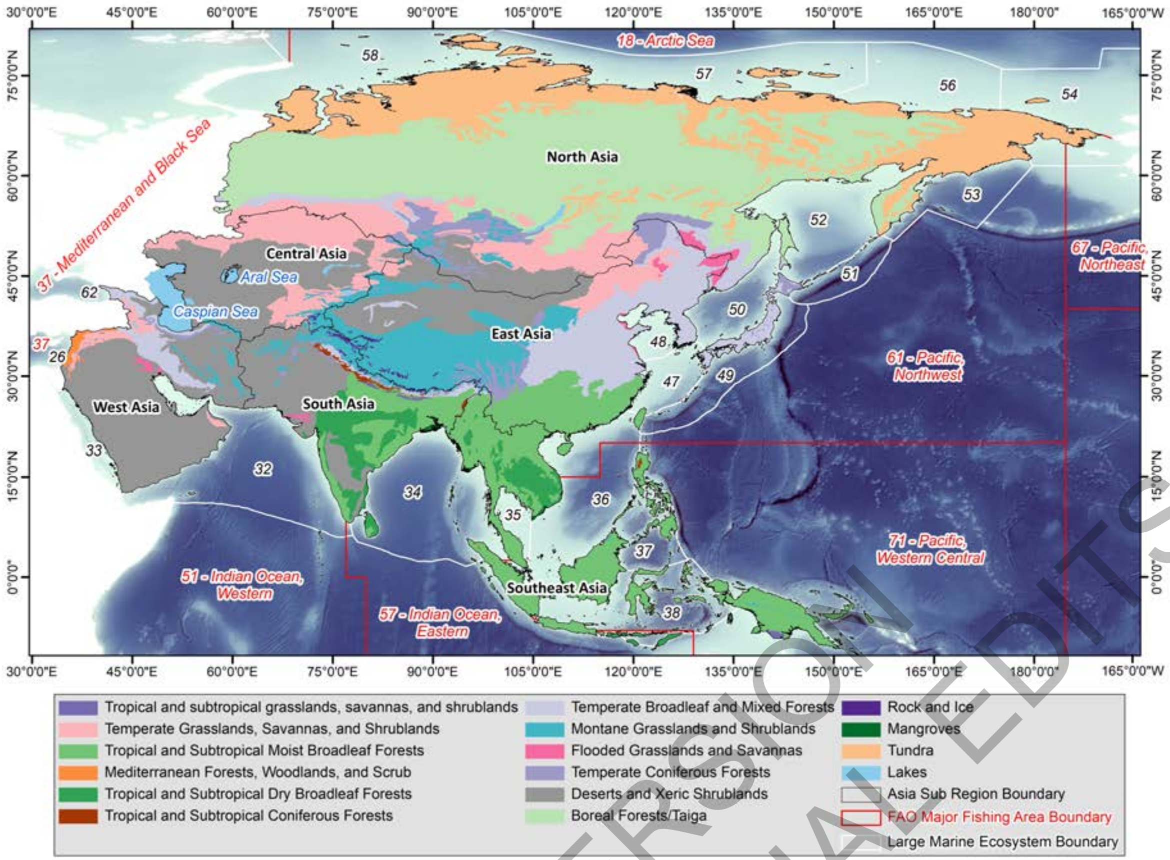

Figure 10.3: Terrestrial Ecoregions, Large Marine Ecosystems and Major Fishing areas of Asia. Large Marine Ecosystems (LMEs) of Asia: 26- Mediterranean Sea, 32- Arabian Sea, 33- Red Sea, 34- Bay of Bengal, 35- Gulf of Thailand, 36- South China Sea, 37- Sulu-Celebes Sea, 38- Indonesian Sea, 47- East China Sea, 48- Yellow Sea, 49- Kuroshio Current, 50- Sea of Japan, 51- Oyashio Current, 52- Sea of Okhotsk, 53- West Bering Sea, 54- Northern Bering - Chukchi Seas, 56- East Siberian Sea, 57- Laptev Sea, 58-Kara Sea, 62- Black Sea, developed after (Olson et al., 2001) (NOAA, 2010), (FAO, 2019)and made with Nature Earth. **Note**: The map is for illustrative purpose only. The boundaries and names shown and the designations used on this map are for the ecoregions and do not imply official endorsement or acceptance by the United Nations.

10.3.3 Demographics / Socio-economic Characteristics

In these six sub-regions of Asia, nature and biophysical impacts of climate change are observed in three climate change hot spots where strong climate signals and high concentrations of vulnerable people are present, namely in semi-arid, glacial fed river basins and mega deltas (Szabo et al., 2016b) (De Souza et al., 2015) (Kilroy, 2015). The impacts of global climate also have profound social implications, threatening human health and well-being, destabilising assets, coping capacities and response infrastructures and substantially increasing the number of socially, economically and psychologically vulnerable individuals and communities (Ford et al., 2015).

Vulnerability to climate change varies by geography and by the economic circumstances of the exposed population (Sovacool et al., 2017). The concentration of population growth in less developed regions means that an increasing number of people live in countries with the least ability to adapt to climate change (Auffhammer and Kahn, 2018). Bangladesh with 163 million people, an example, is one of the most vulnerable countries in the world to climate risks and natural hazards, faces severe floods, cyclones, droughts, heat waves and storm surges on a regular basis (Dastagir, 2015; Hossain et al., 2018; Roy and Haider, 2019).

Differential human vulnerability to environmental hazards results from a range of social, economic, historical, and political factors, all of which operate at multiple scales (Thomas, 2019) (De Souza et al., 2015). Climate change is expected to have serious impacts for people living within these hot spot areas, as observed from loss of food crop yields to disasters such as floods, fluctuations in seasonal water availability, or other systemic effects (De Souza et al., 2015). For instance in South Asia, extreme climatic conditions are threatening food security,thus agro-based economies like India and Pakistan are the most vulnerable to climate change in this regard (Mendelsohn, 2014; Ahmad, 2015; Kirby et al., 2016; Ali et al., 2017).

A broad-based understanding of gendered vulnerability as emerging from poverty and social discrimination as well social cultural practices in different political, geographical and historical settings, apart from climatic variability and environmental/natural risks is central to understanding people's capacities to cope with and adapt to change (Morchain et al., 2015; Yadav and Lal, 2018); (Rao et al., 2019). Studies highlight the fact that disasters do not affect people equally, mostly findings show that insufficient disaster education, inadequate protection measures, and powerful cultural issues, both pre- and post-disaster, increase women's vulnerability during and after disasters (Isik et al., 2015; Reyes and Lu, 2016; Hamidazada et al., 2019) . In particular, cultural issues play a role after disasters by affecting women's security, access to disaster aid, and health care (Raju, 2019). There must be more nuanced understanding and examination of gender, as well as poor, disadvantaged and vulnerable groups in vulnerability and risk assessments (Reyes and Lu, 2016; Reyer, 2017; Xenarios et al., 2019).

Based from the *World Economic Situation and Prospects as of mid-2019 Report*, the region has an estimated 400 million people living in extreme poverty below the threshold of $1.90 a day. At the higher international poverty line of $3.20 a day, the number of poor rises to 1.2 billion, accounting for more than a quarter of the region's total population (Holland, 2019). Beyond monetary measures, indicators of multidimensional aspects of poverty, most notably in Southern Asia indicate a large share of the population still lacks access to basic infrastructure and services (Bank, 2017b).

For instance, South Asia illustrates that on average it could lose nearly 2% of its GDP by 2050, rising to a loss of nearly 9% by 2100 under BAU (Business-as-Usual) scenario (Ahmed and Suphachalasai, 2014). The relationship between economic outcomes and cross-sectional climate variation is confounded by regional heterogeneity, including historical effects of settlement and colonisation (Dell et al., 2014; Newell et al., 2018). Climate change vulnerability may also depend on sufficient employment opportunities in the risk-prone areas, land holding size, gender, education level and family and community size, as observed in Nepal, Thailand, Vietnam (Baul and McDonald, 2015; Lebel L., 2015; Phuong et al., 2018a).

As poor households are constrained in their ability to receive nutrition, schooling and healthcare for their children, this is greatly dampening progress on human capital development and productivity growth, both of which are critical imperatives for sustainable development (Carleton and Hsiang, 2016; Schlenker and Auffhammer, 2018). Studies also have shown negative impacts of climate change on several essential components of people's livelihoods and well-being, such as water supply, food production, human health, availability of land and ecosystems (Roy and Haider, 2019) (Arnell et al., 2016);(Alauddin and Rahman, 2013).
Major population trends of urbanisation and urban area expansion are forecast to take place in Asia region has mentioned demographic change will make humanity more vulnerable to climate change particularly in places with high poverty rates and potentially prone to systemic disruptions in the food system (Puma et al., 2015; d'Amour et al., 2016; d'Amour et al., 2017).

The urban population of the world has grown rapidly from 751 million in 1950 to 4.2 billion in 2018. Asia, despite its relatively lower level of urbanisation, is home to 54% of the world's urban population (United Nations, 2019). Some cities have experienced population decline in recent years. Most of these are located in the low-fertility countries of Asia, where overall population sizes are stagnant or declining, as observed in a few cities in Japan and the Republic of Korea (for example, Nagasaki and Busan) have experienced population decline between 2000 and 2018 (United Nations, 2019). By 2030, the world is projected to have 43 megacities with more than 10 million inhabitants, most of them in developing regions. However, some of the fastest-growing urban agglomerations are cities with fewer than 1 million inhabitants, many of them located in Asia and Africa (United Nations, 2019). Challenges with water supply in many cases exist since decades (Dasgupta, 2015). Climate change increases these challenges (Hoque et al., 2016). As more people inhabit urban areas, the number of people vulnerable to heat stress is thus *likely* to rise, a problem that will be compounded by rising temperatures due to climate change (Acharya et al., 2018). Compared to rural areas, hot temperature risk is even higher in urban regions (Luo, 2018a; Ye, 2018; Setiawati Martiwi Diah, 2021).

The impact of heat in rural areas has been a blind spot so far, particularly for farmers and outdoor labourers who are increasingly exposed to high outdoor temperatures due to increase intensity in agriculture combined with changes in working hours (Tasgaonkar, 2018).

Farmers as a group have shown an increasing number of females over the years due to out-migration of male members in urban areas for employment, in which putting women at more severe risk in the context of climate variability (Singh, 2019). Women are required to acquire new capacities to manage new challenges, including risks from climate change, through capacity-building interventions to strengthen autonomous adaptation measures (Banerjee et al., 2019; James, 2019; Mishra, 2019). However, the overlapping crises of climate change and global public health crisis of COVID-19 represents a major challenge to gender equality and sustainable development (Katherine Brickell, 2020; Sultana, 2021).

For vulnerable populations, such as Indigenous Peoples, older and low-income groups, women, children, people with disabilities, and minorities, the health effects of climate change-related extreme weather events can be especially devastating (McGill, 2016). Such populations may be more susceptible to disease, have pre-existing health conditions or live in areas that do not promote good health or well-being, for instance loss of income and food supply shortages could lead children in rural households to nutritional deprivations that can have both immediate and lifelong impacts (Gleick, 2014; UNICEF, 2015). Children, already susceptible to age-related insecurities, face additional destabilising insecurities from questions about how they will cope with future climate change (Hansen et al., 2013).

[START BOX 10.2 HERE]

Box 10.2: Migration and Displacement in Asia

Migration and displacement in Asia: Migration is a key livelihood strategy across Asia and is driven by multiple factors such as socio-economic changes, increasing climate variability and disaster incidence, and changing aspirations. Displacement denotes a more involuntary movement in reaction to climatic or non-climatic factors. There is *robust evidence, medium agreement* that increased climate variability and extreme events are already driving migration (Gemenne et al., 2015; IDMC, 2020) (Rigaud et al., 2018; IDMC, 2019; Maharjan et al., 2020) (Jacobson et al., 2019; Siddiqui et al., 2019) and *medium evidence, medium agreement* projecting longer-term climate change will increase migration flows across Asia (Abubakar et al., 2018; Rigaud et al., 2018; Hauer et al., 2020; Bell et al., 2021).

Detection and attribution – does climate change drive migration? Ascertaining the role of climate change in migration is difficult and contested (see Cross-Chapter Box MIGRATE in Chapter 7 and RKR H in Chapter 16), with observation-based studies either linking extreme event incidence, weather anomalies, and environmental change with migration numbers or drivers (McLeman, 2014; Singh et al., 2019a; Kaczan and Orgill-Meyer, 2020) and projection studies looking at particular risks such as sea level rise or drought by linking increasing warming (often through RCPs) and population growth. Despite this methodological disagreement on detection and attribution of migration due to climate change, there is *medium evidence, medium agreement* that higher warming and associated changes in frequency and intensity of slow- and rapid-onset events are expected to increase forced migration in the future, especially under less optimistic development pathways (Dasgupta et al., 2014a; Davis et al., 2018; Rigaud et al., 2018; Hauer et al., 2020) but its role is smaller than non-climatic socio-economic drivers of migration (Wodon et al., 2014; Adger et al., 2021).

- *Current migration and displacement*: One in three migrants comes from Asia and the highest ratio of outward migrants is seen from hazard-exposed Pacific countries (Ober, 2019). In 2019, approximately 1,900 disasters triggered 24.9 million new displacements across 140 countries; in particular, Bangladesh, China, India and the Philippines each recorded more than 4 million disaster displacements (IDMC, 2019).Tajikistan, Kyrgyzstan and Russia see significant disaster-associated displacements: e.g. heavy rain-induced flooding in Khatlon (Tajikistan) triggered 5,400 new displacements; landslides in the Jalal-Abad (Kyrgyzstan) saw 4,700 new displacements, while floods in Altai, Tuva, and Khakassia (Russia) displaced 1,500 people. Iran reported highest sub-regional figures with > 520,000 new disaster-related displacements in 2019 (IDMC, 2019). In South East and East Asia, cyclones, floods, and typhoons triggered internal displacement of 9.6 million people in 2019, almost 30% of total global displacements (IDMC, 2019). With most migrants in the region being temporary migrant workers, loss of jobs and wages among them have been particularly severe due to adverse economic climate triggered by COVID-19 (ESCWA, 2020). It has also resulted in large-scale returns of migrant workers and remittances have declined drastically (Khanna, 2020; Li et al., 2021). Remittances to Eastern Europe and Central Asia are expected to decline 16.1 per cent from $57 billion in 2019 to $48 billion in 2020. Remittances in East Asia and the Pacific are estimated to fall 10.5 per cent over the same period, from $147 billion to $131 billion (United Nations, 2020). The COVID-19 pandemic has had significant impacts on migrants (Rajan, 2020) in the region and some countries have targeted migrants in economic stimulus packages or income support programmes; however, access to such support has been heterogenous.

- *Projected migration*: Regional variation is significant across Asia. By one estimate, in South Asia, internal climate migrants, i.e. those migrating due to climate change and associated impacts such as water scarcity, crop failure, sea-level rise, and storm surges, are projected to be 40 million by 2050 (1.8 percent of regional population) under high warming (Rigaud et al., 2018). While methodological critiques remain on projected migration estimates, what is certain is that some countries will be more affected that others; it is estimated that in south Bangladesh, sea level rise can displace 0.9-2.1 million people by direct inundation by 2050 (Jevrejeva et al.; Davis et al., 2018). In South Asia, migration hotspots include the Gangetic Plain and the Delhi–Lahore corridor, coastal cities such as Chennai, Chittagong, Dhaka, and Mumbai, which will be simultaneously exposed to climate change impacts and major migration destinations, and amplified rural–urban migration (Ober, 2019). Importantly, there is *low agreement* on projected numbers (see Boas et al. (2019)) with uncertainties around how local policies and individual behaviours will shape migration choices. Even in high-risk places, people might choose to stay or be unable to move, resulting 'trapped' populations (Zickgraf, 2019; Ayeb-Karlsson et al., 2020). There is currently inadequate evidence to ascertain the nature and numbers of trapped populations currently or in the future.

Implications of migration for adaptation: The evidence on migration and its impacts on adaptive capacity and risk reduction are mixed (Upadhyay, 2014; Banerjee et al., 2018; Szabo et al., 2018; Maharjan et al., 2020; Singh and Basu, 2020). Financial remittances help vulnerable households spread risk through better incomes, expanded networks, and improved assets such as housing, education, and communication technology (Jha et al., 2018; Szabo et al., 2018; Ober, 2019; Maharjan et al., 2020). Benefits from international remittances across the Asia Pacific region were approximately US$276 billion in 2017 (UN, 2018) and in countries such as Kyrgyzstan, Tajikistan, and Nepal remittances were ~25% of national GDP in 2015. However, migration requires a minimum level of resources and liquidity constraints impede internal migration by the poorest households often rendering them immobile (Ayeb-Karlsson et al., 2020; Maharjan et al., 2020). Further, migration does not necessarily mean people move out of risk and often might enter new risks. Notably, migrants in South and South East Asia were severely affected by the compounding crises of disasters and the COVID-19 pandemic and there is emerging evidence that inclusion of universal safety net provisions that embed adaptation planning can reduce vulnerabilities of migrants (Sengupta and Jha, 2020; Cundill et al., 2021; Sultana, 2021).

While there is *robust evidence (medium agreement)* that migration exacerbates gendered vulnerability and work burdens (Banerjee et al., 2019; Singh, 2019; Rao et al., 2020), it is well established that differential vulnerability of migrants intersects with ethnicity, age, and gender; political networks and social capital; and livelihoods in destination areas (Maharjan et al., 2020; Cundill et al., 2021). Across Asia, international and internal migration are changing social norms and household structures, with significant implications for local adaptive capacity (Singh, 2019; Evertsen and van der Geest, 2020; Porst and Sakdapolrak, 2020; Rao et al., 2020).

[END BOX 10.2 HERE]

10.4 Key Systems and Associated Impacts, Adaptation and Vulnerabilities

10.4.1 Energy Systems

10.4.1.1 Regional diversity

Energy consumption of Asia accounts for 36% of the global total at present. China, India and the ASEAN countries have largely contributed to the ever-growing global energy consumption. Asia is predicted to account for 80% of coal, 26% of natural gas and 52% of electricity consumption of the world by 2040 (IEA, 2018). The share of Asia in the global primary energy consumption will increase to 48% by 2050. China continues to be the world's largest energy consumer, and the combined consumption of India and ASEAN will be similar with that of China by that time (IEEJ, 2018).

The energy structure of Asia is dominated by fossil fuels so far. As the trend, the share of coal in China's primary energy consumption is forecasted to sharply decline from 60% in 2017 to around 35% in 2040 (BP, 2019). In contrast, India and ASEAN rely more on coal since coal may meet their soaring energy demand. Accordingly, more than 80% of the global coal will be consumed in Asia by 2050. China will surpass the U.S. in about 10 years to become the world's largest oil consumer. India will then replace the U.S. to be the second largest by late 2040s (IEEJ, 2018).

Around 60% of the incremental electricity demand globally, predicted to double in 2050, will occur in Asia. By that time, electrification rate in Asia will increase to 30% but 40% of electricity demand will be still covered by coal (IEEJ, 2018). Asia accounts for almost half of the growth in global renewable power generation. It is hardly for Japan and Korea to develop additional nuclear power plants as the planned. Whereas, nuclear generation continues to increase quickly in China and the scale will be similar to the entire of OECD by 2040 (BP, 2019). India and Russia's nuclear power sector is also growing fast, e.g., the recent launch of the Akademik Lomonosov offshore nuclear power in Russia.

The rapid growth of energy demand in Asia reinforces the region's position as the largest energy importer (BP, 2019). Around 80% of energy traded globally will be consumed in Asia and the rate of self-sufficiency will decrease from 72% to 63% by 2050. This tendency is especially remarkable for ASEAN, which will become a net importer in early 2020s. Self-sufficiency rate of coal will be maintained at a level of 80%, while that of oil and natural gas will decline significantly. The additional oil imports of the emerging Asian economies will be from North America, the Middle East and North Africa. The main players in Asia for the LNG imports will extend from Japan and Korea to China and India. ASEAN has been a net exporter of natural gas but starts to expand its import due to the increased consumption and resource depletion (IEEJ, 2018).

The increase in energy demand at a rapid rate in these countries cannot thus be attributed only to population growth and rising living standards, but also to increasingly extreme temperature variations. The decrease in precipitation influences energy demand as well, as countries are becoming more dependent on energy-intensive methods (e.g., desalination, underground water pumping) to supply water. Similarly, energy systems are influenced by the way the agriculture sector, mainly in Al Mashrek, relies increasingly on energy-intensive methods (e.g., more fertilisers, different irrigation and harvesting patterns) (Farajalla, 2013).

Climate change has direct and indirect impacts on energy and industrial systems. Climate change has a wide and profound impact on energy systems (energy development, transportation, supply, etc.). With global warming, the energy consumption for heating in winter decreases, while the energy consumption for cooling in summer significantly increases, but the overall energy demand shows an upward trend (Sailor, 2001; Szabo et al., 2018) (*High confidence*). Such demands in summer seasons will by far exceed any energy savings from the decrease in heating demand due to warmer winters. Higher demand for cooling due to hotter temperatures has become a major challenge in the energy sector in all countries. Furthermore, decreased water levels due to lower precipitation reduces hydroelectric output. This is particularly the case for countries such as Syria and Iraq with large hydroelectric capacity (Hamid and Raouf, 2009). Additionally, the decrease in water levels negatively affects low-carbon energy systems such as Concentrated Solar Power (SCP) and thermal generation plants that require regular cooling and cleaning.

Climate change adds extra pressure to current energy infrastructures in most countries where systems failures and blackouts are already common (Assaf, 2009). In the wake of extreme weather events (e.g., heat waves), energy infrastructures remain inadequate to cope. This is particularly the case for countries such as Lebanon, Syria, Jordan, and Palestine, with poor electricity infrastructures (Jordan, 2015). Extreme weather events could generate grave damage to power plants, most being located only a few meters above sea level, as well as power transmission towers and lines. In Lebanon, a small country where there are no Indigenous energy resources, the disruption of shipping of fuel supplies due to extreme weather events is a major risk. Other extreme weather events such as floods and sandstorms expose energy and industrial systems in the coastal areas due to a rise in sea level. Countries of the Arabian Peninsula are projected to experience significant inland flooding as sea levels rise (Hamid and Raouf, 2009). In East Asia wet snow accretion enhanced by global warming often cause damage to electric power lines (Sakamoto, 2000; Ohba and Sugimoto, 2020).

10.4.1.2 Key drivers to vulnerability, observed and projected impacts

The universal energy access is a big challenge for Asia (IEA, 2018). About 230 million Indian people lack access to electricity, and around 800 million still use the solid fuels for cooking (Sharma, 2019). The average electricity access rate in South Asia was 74%, an equivalent of 417 million people without electricity and accounting for more than a third of the global 1.2 billion lacking the access (Shukla et al., 2017). With a total population of nearly 640 million in ASEAN, an estimated 65 million people remain without electricity and 250 million rely on solid biomass as the cooking fuel (IEA, 2017). It is expected to achieve the universal access to electricity by 2030, while 1.6 billion people in Asia will still lack clean energy for cooking (UNESCAP, 2018b).

Asia faces energy security problem even with the rapid growth in production and trade (IEEJ, 2018). Among 13 developing countries with large energy consumption in Asia, 11 expose to high energy security risk (WEC, 2018). This will be a major challenge for the sustainable development of Asia due to the vulnerability to global energy supplies and price volatility (Nangia, 2019). Asia is lack of natural energy resources and has the smallest oil reserve, but largely relies on fossil fuels. The dependency of fossil fuels was as high as 88.3% in China, 72.3% in India, 89.6% in Japan and 82.8% in Korea in 2013 (BP, 2014). Many countries in south Asia rely on a single source to supply more than half of the electricity, i.e., 67.9% from coal for India, 99.9% from hydropower for Nepal, 91.5% from natural gas for Bangladesh and 50.2% from oil for Sri Lanka (Shukla et al., 2017). Additionally, it is still at a very preliminary stage for the cooperation in Asia to create the integrated energy systems for enhancing the overall security due to countries having different strategic plans and lack of cooperation among them on the common concern (Kimura and Phoumin, 2013).

Even energy efficiency is improving, the deployment of low carbon energy like renewables is not sufficient in Asia. To be consistent with the temperature goal of the Paris Agreement, the share of renewables in total energy consumption needs to reach 35% in Asia by 2030. The financing to deploy renewables presents another considerable challenge (UNESCAP, 2018b).

In order to cope with climate change, renewable energy has become the core of energy development and transformation. Since the 1960s, the total solar radiation on the ground in Asia has shown a downward trend as a whole, which is consistent with the change of global total solar radiation on the ground, and has experienced a phased change process of "first darkening and then brightening" (*high confidence*). This conclusion has been further confirmed by ground station observations, satellite remote sensing inversion data and model simulation research (Wang and Wild, 2016; Qin et al., 2018; Yang et al., 2018a).

However, wind speed over most Asian regions is obviously decreasing (*high confidence*). Based on meteorological observation records or reanalysis data, many studies have analysed the variation of near-surface average wind speed in Asia. It is generally found that the wind speed has declined since 1970s, although the declining trend is different (Yang et al., 2012c; Lin et al., 2013; Liu et al., 2014b; Zha et al., 2016; Guo et al., 2017a; Torralba et al., 2017; Wu et al., 2017a; Ohba, 2019). The decline of near-surface wind speed in Asia is consistent with the general decline of global land surface wind speed, among which the frequency of strong winds and the decline of wind speed are more prominent (McVicar et al., 2012; Jiang et al., 2013; Blunden and Arndt, 2017; Wu et al., 2018c). Since the early 2010' s, the average wind speed in the world and some parts of Asia has shown signs of increasing (Li et al., 2018d; Wu et al., 2018c; Zeng et al., 2019), which seems to be an interdecadal variability. Whether it means a change in its trend needs the support of longer observation data.

At the same time, with the increase of the proportion of renewable energy in the power system, the power system will be more vulnerable to climate change and extreme weather and climate events, and the vulnerability and risk of the power system will greatly increase (*medium confidence*).

10.4.1.3 Adaptation options

The overall solution would be to develop a resilient energy system and avoid the risk of unsustainable energy growth in developing Asia. This requires the strategic planning in consistent with the long term climate projection, impact and adaptation (EUEI-PDF, 2017). Although no single policy package would be applicable for all the countries across the region, several measures could be addressed as the common options, including to fortify energy infrastructure and diversify the sources by sufficient investment, to improve energy efficiency for the sector flexibility, and to promote regional cooperation and integration for increasing energy security (UNESCAP, 2018b). Adaptation also includes promoting renewable energy resources, securing local natural gas resources, enhancing water production, and adopting green building technologies. These adaptation measures may help increase the readiness for the anticipated impact of climate change.

The improvement of energy efficiency and demand side management can alleviate supply constraints and thus lower overall required energy capacity. Energy storage, smart grids for the electricity network as well as other flexibility management measures enable this energy demand shifting. Regional integration of energy markets drives productivity increase, cost reduction, new investment, human capability and diversity of energy sources (WEC, 2018). For example, better interconnection of natural gas supply networks among the ASEAN countries enhances gas security in the region. The development of the long planned regional power grid would make large scale renewable projects more viable, and aid the integration of rising shares of wind and solar power (IEA, 2017).

Providing enough investment in energy supply is a top priority to extend the connections to those without access to electricity and satisfy the soaring demand (IEA, 2017). The investment in non-fossil energies like renewables has been expanding to lever economic growth in China, India and Korea. According to the updated estimation of ADB, 14.7 trillion USD will be needed for the infrastructure development in power sector of developing Asia over the 15 years from 2016 to 2030 (ADB, 2017a). The cumulative investment needs of ASEAN for energy supply and efficiency up to 2040 is estimated at 2.7 to 2.9 trillion USD (IEA, 2017). Mobilising investment to such a scale requires significant participation from the private sector and international financial institutions.

Diversifying energy sources increases energy security and thus the resilience of the whole system. The deployment of renewable energy is widely recognised as a crucial measure enhancing energy access and diversity. There remains huge potential for renewable sources in Asia, i.e., India has the massive solar power potential (Shukla et al., 2017). Many renewable technologies, i.e., hydro, wind and solar PV, are becoming competitive and their lifecycle costs may fall below those of coal and natural gas in the near term. Great progresses have been made in Enhanced Geothermal Systems (EGS), and in conventional and unconventional fusion power that China is promoting. Conventional and underground pumped hydro level out supplies for intermittent renewable energy generation.

Substantial room may be fulfilled by increasing the share of renewable energy in overall energy consumption of this region (ADB, 2017a). Access to energy, particularly in rural areas, can reduce climate vulnerability of developing Asia. Due to the high cost of extending the electricity network to rural regions, an alternative way is to develop the off-grid renewable energy systems in these areas. The distributed instead of centralised energy systems can increase the energy access and resilience (EUEI-PDF, 2017).

Some countries in the Arabian Peninsula like the United Arab Emirates (UAE) are adopting an array of approaches to enhance the adaptive capacity of the energy infrastructure and diffuse the risk of climate change over a larger area (e.g., energy efficiency, demand management, storm planning for power plants). In Al Mashrek, building institutional capacity in the energy sector is a necessary first step to mainstream climate change adaptation. Countries such as Lebanon and Jordan have already made progress in mainstreaming climate change adaptation into electricity infrastructure. In the UAE, buildings account for more than 80% of the total electricity consumption. There are currently a set of measures and regulations on building conditions and specifications that are being applied to increase energy efficiency in buildings, but the rehabilitation and upgrading of old buildings still require further efforts (Environment, 2015). In Kuwait, one adaptation measure to dust storms is through the reduction of the proportion of open desert land from 75% to 51%, the increase of protected areas from 8% to 18%, and greenbelt projects in desert areas (Kuwait, 2015). Addressing climate change impact on energy systems in Lebanon, Jordan, Syria, Iraq, and Palestine needs to simultaneously consider other interlinked challenges of population growth, rapid urbanisation, refugee influx, conflict, and geopolitical location. To address these challenges and provide solutions for climate change adaptation, the promotion of multi-stakeholder partnerships is key to breaking the silo approach.

Climate change adaptation measures need to be broadened to fit the scope and depth of mitigation efforts by each country. Risk assessments and vulnerability assessments are in their early stages in the energy and industrial sectors and are not currently based on a comprehensive plan of action. The first step is to undertake comprehensive national assessments of the risks associated with climate change based on existing studies on climate impacts and risks and by making evidence-based decisions on adaptation actions.

10.4.2 Terrestrial and Freshwater Ecosystems

Sub-regional diversity of ecosystems is high in Asia, see 10.2.2. Climatic drivers of Asian terrestrial ecosystems (ATS) change are global warming, precipitation and Asian monsoon alteration, permafrost thawing and extreme events like dust storms. Observed and projected changes in ATS are affected by several interacting factors, which are in play. Non-climatic human-related drivers are change of land use, change of human use of natural resources including species and ecosystems overexploitation and other non-sustainable use, socioeconomic changes, direct impacts of rising GHGs. Ecosystem vulnerability resulted from complex interaction of climatic and non-climatic drivers, species interaction and natural variability of organisms, species and ecosystems is currently poorly understood, and much more work still needs to be done to unravel these multiple stressors (i.e. (Berner et al., 2013; Brazhnik and Shugart, 2015).

10.4.2.1 Observed Impacts

10.4.2.1.1 Biomes and mountain treeline

Changes in biomes in Asia are compatible with a response to regional SAT increase (Arias et al., 2021) (*medium agreement, medium evidence*). Expansion of the boreal forest and reduction of the tundra area is observed for about 60% of latitudinal and altitudinal sites in Siberia (Rees et al., 2020). In Central Siberia, the changes in climate and disturbance regimes are shifting the southern taiga ecotone northward (Brazhnik et al., 2017). In Taimyr, no significant changes in the forest boundary were observed during the last three decades (Pospelova et al., 2017). For the Japanese archipelago, it is suggested that tree community composition change along the temperature gradient is a response to past and/or current climate changes (Suzuki et al., 2015).

Alpine treeline position in Asian mountains in last decades either moves upward in North Asia, or demonstrate multidirectional shifts in Himalaya (*high confidence*). Since AR5, in North Asia new evidence appeared of trees expansion into mountain tundra and steppe, of intensive reproduction and increase of tree stands productivity in last 30-100 years at the upper treeline in Urals Mountains (Shiyatov and Mazepa, 2015; Zolotareva and Zolotarev, 2017; Moiseev et al., 2018; Sannikov et al., 2018; Fomin et al., 2020; Gaisin et al., 2020), in Russian Altai Mountains (Kharuk et al., 2017a; Cazzolla Gatti et al., 2019), in Putorana Mountains (Kirdyanov et al., 2012; Pospelova et al., 2017; Grigor'ev et al., 2019). Lower treelines in southernmost *Larix sibirica* forests in Saur Mountains, Eastern Kazakhstan, suffer from increased in last decades drought stress causing forest regeneration and tree growth decrease, and tree mortality increase (Dulamsuren et al., 2013). In Jeju Island, Korea, recent warming has enhanced *Quercus mongolica* growth at its higher distribution and has led to *Abies koreana* (ABKO) growth reduction at all elevations, except the highest locality. Thus, combination of warming, increasing competition, and frequent tropical cyclone disturbances can lead to population decline or even extinction of ABKO at Jeju Island (Altman et al., 2020). In Himalaya, treeline over recent decades either moves upward (Schickhoff et al., 2015; Suwal et al., 2016; Sigdel et al., 2018; Tiwari and Jha, 2018), or does not show upslope advance (Schickhoff et al., 2015; Gaire et al., 2017; Singh et al., 2018c), or moves downward (Bhatta et al., 2018). In Tibetan Plateau, treeline either shifted upwards or showed no significant upward shift (Wang et al., 2019c). This can be explained by site-specific complex interaction of positive effect of warming on tree growth, drought stress, change in snow precipitation, inter- and intraspecific interactions of trees and shrubs, land use change, especially grazing, and other factors (Liang et al., 2014; Lenoir and Svenning, 2015; Tiwari et al., 2017; Sigdel et al., 2018; Tiwari and Jha, 2018; Sigdel et al., 2020). It is largely unknown how broader scale climate inputs, as pre-monsoon droughts interact with local-scale factors to govern treeline response patterns (Schickhoff et al., 2015; Müller et al., 2016; Bhatta et al., 2018; Singh et al., 2019b).

10.4.2.1.2 Species ranges and biodiversity

Since AR5, new evidences appeared of terrestrial and freshwater species, populations and communities alterations in line with climate change (Arias et al., 2021) (*medium-to-high confidence*) across Asia. In North Asia, temperature increase and droughts promoted spread northward of the current silk moth outbreak (affected nearly 2.5 x 10^6 ha) in Central Siberia dark taiga since 2014 (Kharuk et al., 2017b; Kharuk et al., 2020). Climatic range of Colorado potato beetle, *Leptinotarsa decemlineata* in 1991–2010 expanded east- and northward in Siberia and Russian Far East compared with the 1951–1970 range (Popova, 2014). Climatic range of *Ixodes ricinus*, a vector of dangerous human diseases expanded into Central Asia and south of the Russian Far East (Semenov et al., 2020). A butterfly *Melanargia russiae* in the Middle Urals moved northward (Zakharova et al., 2017). Thrush birds in Western Siberia penetrated northward up to the limits of the sparse woodlands (Ryzhanovskiy, 2019a). Increase in the length of frost-free period observed in the Ilmen Nature Reserve, Middle Urals during the past decades is supposed to be interlinked with changes in the amplitude and frequency of population waves of bank vole (Kiseleva, 2020). In Katunskiy Biosphere Reserve, Russian Altai, in period 2005–2015, alpine plant species have shifted towards higher altitudes by 5.3 m on average (Artemov, 2018).Wild reindeer herds in Taimyr, north of the Central Siberia migrated northward up to the Arctic Sea coast in hot summers 1999–2003 and 2009–2016 because an earlier massive emergence of bloodsucking insects (Pospelova et al., 2017). In Yakutia, the ranges of red deer, elk and the northern pika are expanding, the winter survival of the mouse-like rodents has increased (Safronov, 2016). In the Chukchi Sea, in last decades the average duration polar bears spent onshore increased by 30 days (Rode et al., 2015b) in line with global warming and rapid declining of sea ice habitat (Derocher et al., 2013; Jenssen et al., 2015; Rode et al., 2015a).

In Central Kazakh Steppe, in line with warming, in 2018 there are more "southern" subarid species in the communities and fewer relatively "northern" boreal and polyzonal species of ground beetles (Carabidae) and black beetles (Tenebrionidae) than in 1976-78 (Mordkovich et al., 2020). Present distribution of Asian black birch, *Betula davurica* Pall. in East and North Asia was formed in result of northward expansion during post-Last Glacial Maximum global warming (Shitara et al., 2018). Both upper and low limits of avifauna of two New Guinean mountains, Mt. Karimui and Karkar Island shifted upslope over nearly a half-century since 1965 (Freeman and Freeman, 2014). In Korea, for the last 60 years, the northern boundary line of 63 southern butterfly species moved further north (Government, 2020). Change of butterflies' occurrence in this period was influenced mostly by large-scale reforestation, not by climate change (Kwon et al., 2021). Warming-driven geographical range shift was recorded in 87% of 124 endemic plant species studied in Sikkim Himalaya in period 1849-1850 to 2007-2010 (Telwala et al., 2013). In Darjeeling district, India, significant change in lichen community structure was shown in response to climate change and anthropogenic pollution (Bajpai et al., 2016).

Observed biodiversity or habitat loss of animals or plants was linked to climate change in some parts of Asia (*high confidence*). Climate change, together with human disturbances, caused local extinction of some large- and medium-sized mammals during past three centuries in China (Wan et al., 2019). Climate change showed significant impacts on subalpine plant species at low altitudes and latitudes in Republic of Korea and may impose a big threat to these plant species (Adhikari et al., 2018; Kim et al., 2019c). Climate change has caused habitat loss of amphibians (Surasinghe, 2011), and extinction of some endemic species in Sri Lanka (Kottawa-Arachchi and Wijeratne, 2017).

There are evidences that climate change can alter species interaction or spatial distribution of invasive species in Asia (*high confidence*). Climate warming enhanced the competition ability of the native species (*Sparganium angustifolium*) against the invasive species (*Egeria densa*) in China under a mesocosm experiment in a greenhouse (Yu et al., 2018e). Climate warming increased the non-target effect on a native plant (*Alternanthera sessilis*) by a biological control beetle (*Agasicles hygrophila*) in China due to range expansion of the beetle and change of phenology of the plant (Lu et al., 2015). Climate warming expanded the distribution of invasive bamboos (*Phyllostachys edulis* and *P. bambusoides*) northward and upslope in Japan (Takano et al., 2017), while soil dry-down rates were a key driver of invasion of dwarf bamboo, *Sasa kurilensis* in central Hokkaido above and below treeline (Winkler et al., 2016).

Climate change along with land-use and land cover change influences soil organic carbon content, microbial biomass C, microbial respiration and soil carbon cycle in the Hyrcanian forests, Iran (Soleimani et al., 2019; Francaviglia et al., 2020). In fir forest ecosystems of Tibetan Plateau, winter warming affects the ammonia oxidising bacteria and archaea, thus alters N cycle (Huang et al., 2016). Ecosystem carbon pool in spruce forests of the north-eastern Tibetan Plateau was reduced by ca 25% by deforestation due to recent decades climate warming and wood pasture and logging (Wagner et al., 2015). In Mongolia's forest-steppe, recent decades drought- and land use-induced deforestation reduces ecosystem carbon stock density by c. 40 % (Dulamsuren et al., 2016). In Inner Mongolia, China, the predicted decreases in precipitation and warming for most of the temperate grassland region could lead to pH change, which contributes to a soil C-N-P decoupling that may reduce plant growth and production in arid ecosystems (Jiao et al., 2016).

In Central Asia, in Vakhsh, Kafirnigan, and Kyzylsu river basins, Tajikistan it was shown that temperature stimulate algal species diversity, while precipitation and altitude suppress it (Barinova et al., 2015). In line with warming of Lake Baikal, Russia since the 1990s in the lake's south basin there are shifts in diatom community composition towards higher abundances of the cosmopolitan *Synedra acus* and a decline in endemic species, mainly *Cyclotella minuta* and *Stephanodiscus meyerii* and to a lesser extent *Aulacoseira baicalensis* and *A. skvortzowii* (Roberts et al., 2018). In Gonghai Lake, North China diatom biodiversity increased remarkably from 1966, but began to decline after 1990 presumably in response to rapid climatic warming (Yan et al., 2018).

10.4.2.1.3 Wildfires

Climate change, human activity and lightning determine increase of wildfire severity and area burned in North Asia (*high detection, medium-to-low attribution to climate change*). In North Asia, the extent of fire-affected areas in boreal forest can be millions hectares in a single extreme fire year (Duane et al., 2021) and has nearly doubled between 1970 and 1990 (Brazhnik et al., 2017). During recent decades, number, area and frequency of forest fires increased in Putorana Plateau, north of Central Siberia; in larch-dominated forests of Central Siberia; and in Siberian forests as a whole. This increase is in line with increase of the average annual air temperature, air temperature anomalies, droughts and the length of fire season (Ponomarev et al., 2016; Kharuk and Ponomarev, 2017; Pospelova et al., 2017). The number of forest fires and damaged areas in Gangwon Province and the Yeongdong area in the 2000s increased by factors of 1.7 and 5.6, respectively, compared with the 1990s (Government, 2020). Climate change is not the sole cause of increase of forest fire severity (Wu et al., 2014; Wu et al., 2018d). Ignition is often facilitated by lightning (Canadell et al., 2021), and over 80% of fires in Siberia are *likely* anthropogenic in origin (e.g., (Brazhnik et al., 2017). Gas field development and Indigenous tundra burning practices that may get out of control contribute to fire frequency in forest-tundra of west Siberia (Adaev, 2018; Moskovchenko et al., 2020). Climate change in combination with socioeconomic changes has resulted in an increase of fire severity and area burned in southern Siberia, illegal logging acts to increase fire danger in forest–steppe Scots pine stands (Ivanova et al., 2010; Schaphoff et al., 2016).

10.4.2.1.4 Phenology, growth rate and productivity

In East and North Asia, satellite measurements and ground-based observations in last decades demonstrate either increase of the length of plant growth season over sub-regions or in some territories in line with climate warming, or do not show any significant trend in other territories (*high confidence*). In last decades in China, it was increasing trend in annual mean grassland net primary production (NPP), average Leaf Area Index (LAI) and lengthening of the local growing season (Piao et al., 2015; Zhang et al., 2017b; Xia et al., 2019). Nevertheless, phenology pattern vary across different studies, species and parts of China. In most regions of Northeast China (NEC), start date and length of land surface phenology from 2000 to 2015 had advanced by approximately 1.0 days year^{-1} except for the needle-leaf and cropland areas (Zhang et al., 2017d). For Inner Mongolia, it was shown that neither start of growing season (SOS) nor end of growing season (EOS) presented detectable progressive pattern at the regional level in 1998 – 2012, except for the steppe desert (6% of the total area) (Sha et al., 2016). In the Tianshan Mountains (TM) in China, NPP of only two out of 12 types of vegetation increased in spring, and NPP of only one type increased in autumn from 2000-2003 to 2012-2016 (Hao et al., 2019). In Republic of Korea, from 1970 to 2013 the SOS has been advanced by 2.7 days/decade and the EOS has been delayed by 1.4 day/decade (Jung et al., 2015), during the last decade leaf unfolding was accelerating 1.37 days/year, and the timing of leaf fall was delaying 0.34 day/year (Kim et al., 2019d), cherry blossoms is predicted to flower 6.3 days and 11.2 days earlier after 2090 according to scenarios RCP 4.5 and RCP 8.5, respectively (Government, 2020). On Tibetan Plateau (TP), it was found that the SOS has advanced and EOS has been delayed over the last 30-40 years (Yang et al., 2017). Using NDVI data sets and ground-based budburst data, (Wang et al., 2017c) found no consistent evidence that SOS has been advancing or delaying over the TP during the last two to three decades. The discrepancies in the trends of spring phenology over the TP among different studies could be largely attributed to the use of different phenology retrieval methods. An uncertainty exists with the relationship between land surface phenology and climate change estimated by satellite-derived NDVI because these indices are usually composite products of a number of days (e.g., 16-days) that could fail to capture more details. Besides, due to lack of in situ observations, SOS and EOS at large areas cannot be easy defined (Zhang et al., 2017d).

In North Asia, in the Middle Siberia and south of Western Siberia, growth index of Siberian larch based on tree rings width increased with the onset of warming and changed in antiphase with aridity in 1980s (Kharuk et al., 2018). In Mongolia and Kazakhstan, the last decade's temperature increase promoted radial stem increment of Siberian larch. However, the simultaneous influence of increased temperature, decreased precipitation and increased anthropogenic pressure resulted in widespread declines in forest productivity and reduced forest regeneration, and increased tree mortality (Dulamsuren et al., 2013; Lkhagvadorj et al., 2013b; Lkhagvadorj et al., 2013a; Dulamsuren et al., 2014; Khansaritoreh et al., 2017). In Eastern Taimyr, growing season, the number of flowering shoots, annual increment, success of seed ripening and vegetation biomass have increased considerably in last decades (Pospelova et al., 2017). In Vishera Nature Reserve, Northern Urals Mountains, annual temperature increased in last decades in parallel with summer temperature drop and increase of summer frost numbers. As result, trends of vegetation change are mostly unreliable (Prokosheva, 2017).

Date of arrival of migrant birds to nesting areas, and date of departure from winter areas in Asia are changing consistently with climate change (*medium confidence*). Time of arrival of the gray crow to the Lower Ob river region, northwest Siberia, shifted to earlier dates in period 1970–2017 in consistent with increase of daily average temperatures on the day of arrival (Ryzhanovskiy, 2019b). In Ilmen Nature Reserve, Urals, an earlier arrival of the majority of nesting bird species is not observed last decades. It is explained by the fact that other factors as weather of each spring month of particular years, population density in the previous nesting period, the seed yield of the main feeding plants, and migration of wintering species from adjacent areas determinate long-term dynamics of bird arrival (Zakharov, 2016; Zakharov, 2018). In Yokohama, Japan observations since 1986 revealed that arrival of six winter bird species became later and departure earlier than in the past in line with warmer temperatures (Kobori et al., 2012; Cohen et al., 2018). Part of papers analysed corroborate that earlier start and late end of phenological events in Asia are associated with global warming, however another part of papers does not confirm such a connection. Comparison and synthesis of results is impeded by usage of different metrics, measurement methods and models (e.g., (Hao et al., 2019)). Relative contribution of climatic stress and other factors to phenology and plant growth trends are poorly understood (e.g., (Andreeva et al., 2019)).

10.4.2.2 Projected Impacts

10.4.2.2.1 Biomes and mountain treeline

Across Asia, under a range of RCPs and other scenarios rising temperature is expected to contribute to northward shift of biome boundaries and upward shift of mountain treeline (*medium confidence*). Northward shift and area change of bioclimatic zones in Siberia (Anisimov et al., 2017; Torzhkov et al., 2019) and NE Asia (Choi et al., 2019) are projected. Projected changes in vegetation in China at the end of the 21st century revealed that the area covered by cold-dry potential vegetation decreases as the area covered by warm-humid potential vegetation increases (Zhao et al., 2017a). Forest expansion into mountain tundra of the Northern Urals is expected (Sannikov et al., 2018). In Republic of Korea, projected under RCP 4.5 and RCP 8.5 in 2070s suitable area loss of six subalpine tree species, namely, Korean fir, Khingan fir, Sargent juniper, Yeddo spruce, Korean yew, and Korean arborvitae range from 17.7% ± 20.1% to 65.2% ± 34.7%, respectively (Lee et al., 2021b). Korean fir forests would be replaced by temperate forests at lower elevations, while would continuously persist at the highest elevations on Mt. Halla, Jeju Island, Republic of

Korea (Lim et al., 2018). Himalayan birch at its upper distribution boundary either projected to move upward (Schickhoff et al., 2015; Bobrowski et al., 2018), or considered to downslope as a response to global-change-type droughts (Liang et al., 2014). Upward shift in elevation of bioclimatic zones, decreases in area of the highest elevation zones, large expansion of the lower tropical and sub-tropical zones can be expected by the year 2050 throughout the transboundary Kailash Sacred Landscape of China, India and Nepal, and *likely* within the Himalayan region more generally (Zomer et al., 2014).

In North Asia, it is projected a shift in the dominant biomes from conifers to deciduous species across Russia after 20 years of altered climate conditions (Shuman et al., 2015). In Southern Siberia, Brazhnik and Shugart (2015) projected shift from the boreal forest to the steppe biome. Rumiantsev et al. (2013) also project positive northward shift of vegetation boundaries for greater part of Western Siberia (WS) in line with warming, however no shift for the north of WS, and negative shift for Southern Urals and North-western Kazakhstan are projected for 2046-2065. The replacement of forest-steppe with steppe at the lower treeline in Southern Siberia is projected (Brazhnik and Shugart, 2015), and retreat of larch forests from the southernmost strongholds of boreal forest in the Eastern Kazakhstan is expected as part of a global process of forest dieback in semiarid regions (Dulamsuren et al., 2013). In North Asia, tree growth is intertwined with permafrost, snowpack, insect outbreaks, wildfires, seed dispersal and climate (e.g. (Klinge et al., 2018)). It is challenging to isolate the affects of individual factors, particularly since they can feedback on one another in unanticipated ways because underlined mechanisms are not understood well (Berner et al., 2013; Brazhnik and Shugart, 2015). The accuracy of treeline shift projections is limited because projections are based on vegetation models which do not consider all the factors (Tishkov et al., 2020). Regional vegetation model structure and parameterisation can affect model performance, and correspondent projections can differ significantly (Shuman et al., 2015).

10.4.2.2.2 Species ranges and biodiversity

Considerable changes of plant and animal species distribution under warming stress until 2100 are expected in Asia (*high confidence*). In East Asia, *Cunninghamia lanceolate*, a fast growing and wide distributed in China coniferous timber species, is projected to increase distribution, to decrease the establishment probability and to reduce total NPP by 2050s (Liu et al., 2014c). In monsoon Asia, by the end of the 21st century, NPP is projected to increase by 9–45 % (Ito et al., 2016). Under climate change in the Korean Peninsula (KP), potential habitat for *Abies nephrolepis* is the northern part of KP, *A. koreana* disappear from Jeju Island and shrink significantly in the KP (Yun et al., 2018), while evergreen forest would expand to the northern part of KP (Koo et al., 2018; Lim et al., 2018). It is expected that under projected warming fig species in China will expand to higher latitudes and altitudes (Chen et al., 2018c). In Japan, under AIB scenario 89% of the area currently covered by *Fagus crenata*-dominant forest type to be replaced in the future by *Quercus spp*.-dominant forest types (Matsui et al., 2018). Current trends of climate change will reduce distribution of tall, 2-2.5 m height herb communities in Japan, and will increase suitable for them area in the Russian Far East (Korznikov et al., 2019). A range expansion of *Lobaria pindarensis*, an endemic in HKH region epiphytic lichen, is projected to the north-east and to higher altitudes in response to climate change, although the species' low dispersal abilities and the local availability of trees as a substratum will considerably limit latitudinal and altitudinal shifts (Devkota et al., 2019).

Climatic range of Italian locust (*Calliptamus italicus* L.) under the RCP4.5 will expand north- and eastward to Siberia, Russian Far East and Central Asia (Popova et al., 2016). In Krasnoyarsk Krai, Siberia it is projected that the needle cast disease caused by fungi from the genus *Lophodermium* Chevall. in the Scots pine nurseries would shift northwards up to 2080 under A2 and B1 scenarios (Tchebakova et al., 2016). All four RCP scenarios showed northward expansion of vulnerable regions to pine wilt disease in China, Korea, Russian Far East, and Japan under future climate conditions in 2070 (Hirata et al., 2017), and in 2026-2050 in Japan (Matsuhashi et al., 2020). It should be noted that disease expansion depends not only on climatic factors, but also on the dispersal capacity of insect vectors, the transportation of infected logs to non-infected regions, and susceptibility of host trees (e.g. (Gruffudd et al., 2016)). Suitable habitat area of snow leopard *Panthera uncia* is projected to increase for 20% under the IPCC Scenario A1B by 2080: for the seven northernmost snow leopard range states (Afghanistan, Tajikistan, Uzbekistan, Kyrgyzstan, Kazakhstan, Russia, and Mongolia) the suitable habitat area will increase, while habitat loss is expected on the south slope of the Himalaya and the south-eastern Tibetan Plateau (Farrington and Li, 2016). Climate change projected under four RCP scenarios will not affect the distribution patterns of Turkestan Rock Agama *Paralaudakia lehmanni* (Nikolsky 1896) (Sancholi, 2018). In Iran, among 37 studied species of plants and animals, ranges of 30 species are expected to shrink and range of seven species are expected to increase by 2030-2099 under climate change stress (Yousefi et al., 2019).

Future climate change would cause biodiversity and habitat loss in many parts of Asia using modelling approaches (*high confidence*). Warren et al. (2018) projected that extirpation risks terrestrial taxa (plants, amphibians, reptiles, birds and mammals) from 2°C to 4.5°C global warming in 12 priority Places of Asia under the assumptions of without adaptation (dispersal) by 2080s is from 12.2-26.4% to 29-56% (Table 10.1, Figure 10.4).Under different scenarios, future climate change could reduce the extent of a suitable habitat for giant pandas (Fan et al., 2014), the moose (*Alces alces*) (Huang et al., 2016), black muntjac (*Muntiacus crinifrons*) (Lei et al., 2016), the Sichuan snub-nosed monkey (*Rhinopithecus roxellana*) (Zhang et al., 2019d) in China; Persian leopard (*Panthera pardus saxicolor*) in Iran (Ashrafzadeh et al., 2019a), Bengal tiger (Mukul et al., 2019), and four tree snail species (*Amphidromus*) in Thailand (Klorvuttimontara et al., 2017). However, climate change would have little impact on the habitats of Asian elephant, but would cause extinction of Hoolock gibbon in Bangladesh by 2070 (Alamgir et al., 2015). Climate change would increase the distribution of Mesopotamian spiny-tailed lizard (*Saara loricate*) in Iran (Kafash et al., 2016). Future climate change would reduce suitable habitat of protected plants (Zhang et al., 2014), *Polygala tenuifolia* Wild (Lei et al., 2016), relict species in East Asia (Tang et al., 2018), and tree *Abies* (Ran et al., 2018) in China; two threatened medicinal plants (*Fritillaria cirrhosa* and *Lilium nepalense*) in Nepal (Rana et al., 2017); a medicinal and vulnerable plant species *Daphne mucronata* (Abolmaali et al., 2018) and *Bromus tomentellus* in Iran (Sangoony et al., 2016); a valuable threatened tree species *Dysoxylum binectariferum* in Bangladesh (Sohel et al., 2016); plant diversity in Korea (Lim et al., 2018).

Impact of future climate change on invasive species may be species- or region-specific (*medium confidence*). Climate change would promote invasion of a highly invasive aquatic plant *Eichhornia crassipes* (You et al., 2014), *Ambrosia artemisiifolia* (Qin et al., 2014), alligator weed (*Alternanthera philoxeroides*) (Wu et al., 2016), invasive alien plant *Solidago canadensis* (Xu et al., 2014), three invasive woody oil plant species (*Jatropha curcas, Ricinus communis,* and *Aleurites moluccana*) (Dai et al., 2018), 90 of ~150 poisonous plant species (Zhang et al., 2017a) in China; six mostly serious invasive species (*Ageratum houstonianum* Mill., *Chromolaena odorata* (L.) R.M. King & H. Rob., *Hyptis suaveolens* (L.) Poit*., Lantana camara* L*., Mikania micrantha* Kunth*,* and *Parthenium hysterophorus* L.) in Nepal (Shrestha et al. 2018), eleven invasive plant species in Western Himalaya (Thapa et al., 2018), alien plants in Georgia (Slodowicz et al., 2018), the invasive green anole (*Anolis carolinensis*) in Japan (Suzuki-Ohno et al., 2017), the Giant African Snail in India (Sarma et al., 2015), a major insect vector (*Monochamus alternatus*) of the pine wilt disease (Kim et al., 2016b) and melon thrips (*Thrips palmi* Karny) (Park et al., 2014) in Korea. In contrast, a few studies projected that the climate change would inhibit the invasion of one exotic species (*Spartina alterniflora*) (Ge et al., 2015), alien invasive weeds (Wan et al., 2017), invasive plant *Galinsoga parviflora* (Bi et al., 2019), an invasive species *Galinsoga quadriradiata* (Yang et al., 2018b) in China; two invasive plants (*Chromolaena odorata* and *Tridax procumben*s) in India (Panda and Behera, 2019).

Five of 15 endemic freshwater fish species in Iran will lose some parts of their current suitable range under climate change by 2070 (Yousefi et al., 2020). In line with projected large increases in mean water temperature, it is projected the strongest increase in exceeded frequency and magnitude of maximum temperature tolerance values for freshwater minnow (*Zacco platypus*) in East Asia for 2031 to 2100 (Van Vliet et al., 2013). Climate change under A1B scenario is projected to decrease diversity (-0.1%) along with increased local richness (+15%) and range size (+19%) of stream macroinvertebrates in the Changjiang River catchment, south-east China for the period 2021 to 2050, while land-use change was predicted to have the strongest negative impact (Kuemmerlen et al., 2015). Asian clam *Corbicula fluminea* (Müller, 1744), an invasive species native to southeast China, Korea, and south-eastern Russia, is projected to invade to South-east Asia under all four RCP scenarios for 2041–2060 and 2061–2080 periods (Gama et al., 2017). Projected sea level rise, related aquatic salinisation, and alteration in fish species composition may have a negative impact on poor households in Southwest Coastal Bangladesh (Dasgupta et al., 2017a).

10.4.2.2.3 Wildfires

Under regional projections for North Asia, warmer climate will increase forest fire severity by the late 21st century (*medium confidence*). For south taiga in Tuva Republic, central Siberia, in a warmer climate, both the annual area burned and fire intensity will increase by 2100. For middle taiga in Irkutsk Region, the annual area burned and the crown: ground fire fraction will increase by late 21st century against historical

(1960-1990) estimate. This moves forest composition toward greater contribution of hardwoods (*Betula* spp., *Populus* spp.) (Brazhnik et al., 2017). This shifting was also proved by observations in the Northern Mongolia, where boreal forest fires *likely* promote the relative dominance of *B. platyphylla* and threaten the existence of the evergreen conifers, *Picea obovata*, and *Pinus sibirica* (Otoda et al., 2013). For Tuva Republic, warming ambient temperatures increase the potential evapotranspiration demands on vegetation, but if no concurrent increase in precipitation occurs, vegetation becomes stressed and either dies from temperature-based drought stress or more easily succumbs to mortality from insects, fire, pathogens, or wind throw (Brazhnik et al., 2017). Although Torzhkov et al. (2019) also projected fire risk (FR) increase in Tuva Republic, they expect FR decrease in Irkutsk Region and Yakutia under RCP 8.5, and FR decrease in major part of central and eastern Siberia under RCP 4.5 for 2090-2099. This discrepancy is due to differences in models, climate projections, fire severity metrics and other assumptions. According to global projections, fire risk will increase in Central Asia, Russia, China and India under a range of scenarios (Sun et al., 2019).

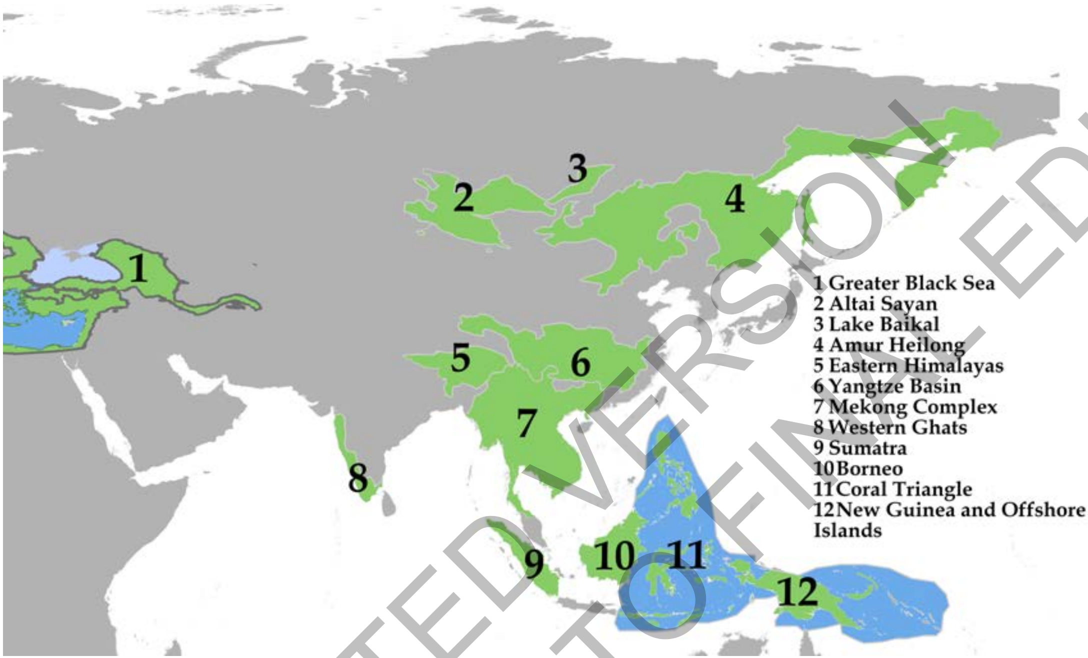

Figure 10.4. Location of Priority Places in Asia (modified from: Warren et al. (2018)

Table 10.1: Projected extirpation risks, % of taxa (plants, amphibians, reptiles, birds and mammals) for 2°C and 4.5°C global warming in Priority Places in Asia, without adaptation by 2080s (from: Warren et al. (2018))

Priority Places	**2°**	**4.5°**
Mekong	26.4	55.2
Baikal	22.8	49.5
Yangtze	20	42.6
Coral Triangle	19.2	41.8
W Ghats	18.8	41.67
New Guinea	19.8	41.2
Atlai-Syan	18.6	37
Sumatra	16.8	37
Borneo	17.6	36.8
Amur	14.2	35.6
Eastern Himalayas	12.2	29
Black sea	26.2	56

10.4.2.3 Vulnerabilities to Key Drivers

Both natural and managed ecosystems, ecosystem services and livelihoods in Asia will potentially be substantially impacted by changing climate (Wu et al., 2018d). There will be increased risk for biodiversity, particularly many endemic and threatened species of fauna and flora already under environmental pressure from land use change and other regional and global processes (Zomer et al., 2014; Rashid et al., 2015; Choi et al., 2019). Biomes shift not only serves as a signal of climate change but also provides important information for resources management and ecotone ecosystem conservation. A widespread upward encroachment of subalpine forests would displace regionally unique alpine tundra habitats and possibly cause the loss of alpine species (Schickhoff et al., 2015). In the North Asia, emissions from fires reduce forest ability to regulate climate. A warmer and longer growing season will increase vulnerability to fires, although fires can be attributed both to climate warming and to other human and natural influences. Recent field-based observations revealed that the forests in southern Siberia are losing their ability to regenerate post fire and other landscape disturbances under a warming climate (Brazhnik et al., 2017). Data support the hypothesis of climate-driven increase of fire frequency in boreal forests with the possible turning of boreal forests from carbon sink to a carbon source (Ponomarev et al., 2016; Schaphoff et al., 2016; Brazhnik et al., 2017; Ponomarev et al., 2018), however warming resulted from forest fire is partly compensated by cooling in response to increased surface albedo of burned areas in snow-on period (Chen and Loboda, 2018; Chen et al., 2018a; Jia et al., 2019; Lasslop et al., 2019).

10.4.2.4 Adaptation Options

Modelling of the interactions between climate-induced vegetation shifts, wildfire and human activities can provide keys to how people in Asia may be able to adapt to climate change (Kicklighter et al., 2014; Tian et al., 2020). Conservation and sustainable development would benefit from being tailored and modified considering the changing climatic conditions and shifting biomes, mountain belts and species ranges (Pörtner et al., 2021). Expanding the nature reserves would help species conservation; to facilitate species movements across climatic gradients, increase of landscape connectivity can be elaborated by setting up habitat corridors between nature reserves and along elevational and other climatic gradients (Brito-Morales et al., 2018; D'Aloia et al., 2019; United Nations Climate Change Secretariat, 2019). Assisted migration of species should be considered for isolated habitats as mountain summits or where movements are constrained by poor dispersal ability. Introducing seeds of the species to new regions will help to protect them from the extinction risk caused by climate change (Mazangi et al., 2016). In Asian boreal forest, a strategy and an integrated programmes should be developed for adaptation of forests to global climate change, including sustainable forest management, firefighting infrastructure and forest fuel management, afforestation, institutional, social, and other measures in line with SDG 15 'Life on Land' (Isaev and Korovin, 2013; Kattsov and Semenov, 2014; Government, 2020). Improvements in forest habitat quality can reduce the negative impacts of climate change on biodiversity and ecosystem services (Choi et al., 2021). Adaptation options for freshwater ecosystems in Asia include increasing connectivity in river networks, expanding protected areas, restoring hydrological processes of wetlands and rivers, creating shade to lower temperatures for vulnerable species, assisted translocation and migration of species (Hassan et al., 2020; IPCC, 2021b). Reducing of non-climate anthropogenic impacts can enhance the adaptive capacity of ecosystems (Tchebakova et al., 2016).

[START BOX 10.3 HERE]

Box 10.3: Case Study on Sand and Dust Storm, Climate Change, in West Asia, Iran

West Asia Region, especially Tigris-Euphrates alluvial plain, has been recognised as one of the most important dust source areas in the world (Cao et al., 2015). The inhabitants of each of these settlements have experienced a decline in dust storms in recent decades, since the late 1980s at Nouakchott, since 2004 at Zabol, and since the late 1970s at Minqin. Iran is mostly arid or semiarid, with deserts making up at least 25 million hectares of the country's area (NASA, 2018). Iran is experiencing unprecedented climate-related problems such as drying of lakes and rivers, dust storms, record-breaking temperatures, droughts, and floods (Vaghefi et al., 2019). There are three key factors responsible for the generation of sand and dust storms – strong wind, lack of vegetation and absence of rainfall (EcoMENA, 2020). It seems that it is closely related to the heating surface and the occurrence of local dry instabilities (Ghasem et al., 2012). According to

EcoMENA sand and dust storms cause significant negative impacts on society, economy and environment at local, regional and global scale (EcoMENA, 2020). The seasonality of the numbers of dusty days (NDD) in Iran shows the highest frequency for summer followed by the spring and autumn seasons (Modarres and Sadeghi, 2018). In the past decade, West Asia has witnessed more frequent and intensified dust storms affecting Iran and Persian Gulf countries (Nabavi et al., 2016). In terms of long-term frequency of dust events, observational analyses show an overall rising trend of the frequency of Iran's dust events in recent years (Alizadeh-Choobari et al., 2016). Results showed that there was a direct relationship between dust event and drought and years having intensive drought (Dastorani and Jafari, 2019). Compared to the period of 1980–2004, in the period of 2025–2049, Iran is *likely* to experience more extended periods of extreme maximum temperatures in the southern part of the country, more extended periods of dry (for ≥120 days: precipitation <2mm, Tmax ≥30°C) as well as wet (for ≤3 days: total precipitation ≥110mm) conditions, and higher frequency of floods (Vaghefi et al., 2019). The slope of precipitation, in West Asia region showed that during the period of 2016-2045 in January, February, July and August, precipitation would increase and decrease in other months of the year (Ahmadi et al., 2018). Temperatures in Central Asia have risen significantly within the last decades whereas mean precipitation remains almost unchanged (Haag et al., 2019). However, climatic trends can vary greatly between different sub-regions, across altitudinal levels, and within seasons (Haag et al., 2019).

[END BOX 10.3 HERE]

10.4.3 Ocean and Coastal Ecosystems

Coastal habitats of Asia are diverse and the impacts of climate change including rising temperature, ocean acidification and sea level rise has been known to affect the services and the livelihood of people depending on it. The risk of irreversible loss of many marine and coastal ecosystems increases with global warming, especially at 2°C or more (*high confidence*) (IPCC, 2018b). In South China Sea coral growth and sea surface temperature (SST) showed regional long tern trends and inter-decadal variations while coral growth is predicted to decline by the end of this century (Yan et al., 2019). Increasing human impacts have also been found to reduce coral growth (Yan et al., 2019). In the SCS, nearly 571 coral species, have been severely impacted by global climate changes and anthropogenic activities (Huang et al., 2015a).

The 2014–2017 global-scale coral bleaching event (GCBE) resulted in very high coral mortality on many reefs, rapid deterioration of reef structures, and far-reaching environmental impacts (Eakin et al., 2019). The thermally tolerant Persian Gulf corals (Coles and Riegl, 2013) are facing an increasing frequency of mass bleaching (Riegl et al., 2018) and each event leaves a substantial long-term impact on coral communities (Burt, 2014) with low capacity for recovery indicating a bleak future for Persian Gulf reefs (Burt et al., 2019).

One of the probable results of global warming is rising high seas level. Scientists believe that increasing greenhouse gases (earth temperature controller) is the reason of this global warming and by using satellite measurements, have forecasted averagely 1-2 mm for rising high seas level (Jafari et al., 2016). The level of thermal stress (based on a degree heating month index, DHMI) at these locations during the 2015–2016 El Niño was unprecedented and stronger than previous ones (Lough et al., 2018) Persian Gulf the reef-bottom temperatures in 2017 were among the hottest on record, with mean daily maxima averaging 35.9 ± 0.10C across sites, with hourly temperatures reaching as high as 37.7o C (Riegl et al., 2018). About 94.3% of corals bleached, and two-thirds of corals suffered mortality in 2017 (Burt et al., 2019). In 2018 coral cover averaged just 7.5% across the southern basin of the Persian Gulf. This mass mortality did not cause dramatic shifts in community composition as earlier bleaching events had removed most sensitive taxa. An exception was the already rare Acropora which were locally extirpated in summer 2017 (Burt et al., 2019). During 2008-2011 also the coral communities of Musandam and Oman have shown changes depending on the stress tolerance levels of the species and the local environmental disturbance level (Bento et al., 2016).

Health and resilience of corals have been found to be associated with beneficial microorganisms of coral (BMC) which alter during environmental stress. Increased seawater temperature has been found to affect the functioning of symbiotic algae of corals (Lough et al., 2018) (Gong et al., 2019) and its bacterial consortia leading to coral bleaching and mortality (Bourne et al., 2016); (Peixoto et al., 2017); (Bernasconi et al., 2019); (Motone et al., 2020).

Coral reefs were found to be affected differentially during bleaching episodes and those species which survived had more stress tolerant symbionts and higher tolerance to thermal changes (Majumdar et al., 2018); (Thinesh et al., 2019) (van der Zande et al., 2020). Rare thermally tolerant algae and host species-specific algae may play important roles in coral bleaching (van der Zande et al., 2020). Along the Indian coast, coral reefs of Palk Bay (Bay of Bengal), varied bleaching and recovery pattern among coral genera was observed during the 2016 bleaching episode (Thinesh et al., 2019). Bleaching was high in Acropora (86.36%), followed by Porites (65.45%), while moderate to no bleaching was observed in Favites Symphyllia, Favia, Platygyra and Goniastrea.

Presence of stress-tolerant symbiont Durusdinium (Clade D) during the post bleach period indicated the high adaptive capacity of Acropora in tropical waters (Thinesh et al., 2019). Also Porites sp. were found to have higher thermal thresholds and showed good resilience to bleaching than species like Fungiid sp. (Majumdar et al., 2018). In Philippines, during the 2010 bleaching event, the size structure of the mushroom coral was found to be affected (Feliciano et al., 2018). In Indonesia , it was found that branching coral diversity may decrease relative to massive, more resilient corals (Hennige et al., 2010). This would have large-scale impacts upon reef bio-diversity and ecosystem services, and reef metabolism and net reef accretion rates, since massive species are typically slow growers (Hennige et al., 2010).

Macro-tidal coral reefs are particularly sensitive to medium to long-term changes in sea-level Andaman trenches (Simons et al., 2019). Data were compiled from 11 cities throughout East and Southeast Asia, with particular focus on Singapore, Jakarta, Hong Kong, and Naha (Okinawa) highlights several key characteristics of urban coral reefs, including "reef compression" (a decline in bathymetric range with increasing turbidity and decreasing water clarity over time and relative to shore), dominance by domed coral growth forms and low reef complexity, variable city-specific inshore-offshore gradients, early declines in coral cover with recent fluctuating periods of acute impacts and rapid recovery, and colonisation of urban infrastructure by hard corals (Heery et al., 2018).

In Taiwan, Province of China, calcification rate of the model reef coral *Pocillopora damicornis* was higher in coral reef mesocosms featuring seagrasses under ocean acidification conditions at 25 and 28°C. The presence of seagrass in the mesocosms helped to stabilise the metabolism of the system in response to simulated climate change (Liu et al., 2020a).

Increase in host susceptibility, pathogen abundance or virulence has led to higher prevalence and severity of coral diseases and lead to decline and changes in coral reef community composition (Maynard et al., 2015) . Relative risk has been found to be high in the province of Papua in Indonesia, Philippines, Japan, India, northern Maldives, the Persian Gulf and the Red Sea. For the combined disease risk metric, relative risk was considered lower for locations where anthropogenic stress was low or medium, condition found for some of these locations in Thailand (Maynard et al., 2015).

Degradation and loss of coral reefs can affect about 4.5 million people South East Asia and Indian Ocean (Lam et al., 2019). In the coral reef fisheries sector, there are about 3.35 million fishers in Southeast Asia and 1.5 million fishers in the Indian Ocean (Teh et al., 2013). The economic loss under different climate change scenarios and fishing effort were estimated to range from US$27.78 to US$31.72 million annually in Nha rang Bay, Vietnam. A survey conducted in Taiwan, Province of China, showed that the average annual personal willingness to pay was US$35.75 and total annual willingness to pay as US$0.43 billion. These high values indicate the need to preserve these coral reef ecosystems (Tseng et al., 2015). In Bangladesh the coral reef of St. Martin's Island contributes 33.6 million USD/year to the local economy climate change along with other anthropogenic activities has been identified as a threat these habitats (Rani et al., 2020a).

Mitigation of global warming has been identified to be essential to maintain healthy coral reef ecosystems of Asia (Comte and Pendleton, 2018); (Heery et al., 2018); (Yan et al., 2019); (Lam et al., 2019). Restoration of reefs (Nanajkar et al., 2019) and building resilience through multiple mechanisms, such as innovative policy combinations, complemented by environmental technology innovations and sustained investment (Hilmi et al., 2019); (McLeod et al., 2019) are suggested.

An ecosystem-based approach to managing coral reefs in the Gulf of Thailand is needed to identify appropriate marine protected area networks and to strengthen marine and coastal resource policies in order to build coral reef resilience (Sutthacheep et al., 2013). Scope to develop novel mitigation approaches toward coral protection through the use of symbiotic bacteria and their metabolites (Motone et al., 2018); (Motone et al., 2020) has been suggested. Coral culture and transplantation within the Gulf are feasible for helping maintain coral species populations and preserving genomes and adaptive capacities of Gulf corals that are endangered by future thermal stress events (Coles and Riegl, 2013). Greater focus on understanding the flexibility and adaptability of people associated with coral reefs, especially in a time of rapid global change (Hoegh-Guldberg et al., 2019) and a well-designed research program for developing a more targeted policy agenda (Lam et al., 2019). is also recommended. Cutting carbon emissions (Bruno and Valdivia, 2016) and limiting warming to below 1.5˚C is essential to preserving coral reefs worldwide and protecting millions of people (Frieler et al., 2013) (Hoegh-Guldberg et al., 2017). Many visitors to coral reefs have high environmental awareness and reef visitation can both help to fund and to encourage coral reef conservation (Spalding et al., 2017).

The largest mangrove forests are in Asia contributing to about 42% of the world's mangroves and this includes Sundarbans the world's largest remaining contiguous mangrove forest (Dasgupta et al., 2020.). Mangrove ecosystems are rich in biodiversity. The ecosystems are supported and maintained by both flora and a large array of living things, which include mammals, birds, fish, crustaceans, shrimps, insects and microbes (Tropical Coastal Ecosystems Portal. Available from http://www.nies.go.jp/TroCEP/index.html. Accessed 08-Oct. 2020). Contemporary rates of mangrove deforestation are lower than in the late twentieth century (Gandhi and Jones, 2019); (Friess et al., 2019). However, some areas in Asia continue the trend. Myanmar is the primary mangrove loss hotspot in Asia, exhibiting 35% loss from 1975–2005 and 28% between 2000–2014. Rates of loss in Myanmar were four times the global average from 2000–2012. The Philippines is additionally identified as a loss hotspot, with secondary hotspots including Malaysia, Cambodia and Indonesia (Gandhi and Jones, 2019).

Mangrove deforestation is expected to increase as many tropical nations utilise mangrove areas for economic security. Increased river damming would reduce fluvial sediment sources to the coast making mangroves more vulnerable SLR and uncertain climate with extreme oscillations can create unstable conditions for survival and propagation of mangrove (Friess et al., 2019).

Valuation of ecosystem services of mangroves indicated that they prevent more than 1.7 billion US$ in damages for extreme events (1-in-50-year) in Philippines (Menéndez et al., 2018). They reduce flooding to 613,500 people/year, 23% of whom live below the poverty line and avert damages to 1 billion US$/year in residential and industrial property. Mangroves have also become very popular as source of livelihood in Asia through tourism (Dehghani et al., 2010),(Kuenzer and Tuan, 2013), (Spalding and Parret, 2019) (Dasgupta et al., 2020.) and they support fisheries (Hutchison et al., 2014).

Mangroves, tidal marshes and seagrass meadows (collectively called coastal blue carbon ecosystems) sequester carbon dioxide from the atmosphere continuously over thousands of years, building stocks of carbon in biomass and organic rich soils. Carbon dynamics in mangrove-converted aquaculture in Indonesia indicated that the mean ecosystem carbon stocks in shrimp ponds were less than half of the relatively intact mangroves (Arifanti et al., 2019). Conversion of mangroves to shrimp ponds in the Mahakam Delta resulted in a carbon loss equivalent to 226 years of soil carbon accumulation in natural mangroves. In Philippines, abandoned fishpond reversion to former mangrove was found to be favourable for enhancing Climate Change Mitigation and Adaptation (Duncan et al., 2016). Integrated mangrove-shrimp farming, with deforested areas not exceeding 50% of the total farm area has been suggested to support both carbon sequestration as well as livelihood (Ahmed et al., 2018).

Globally the extent of blue carbon ecosystem has been estimated as 120380 km^{-2}, with highest spread by mangroves 114669 km^{-2}, (95.3%) followed by seagrass meadows 2201 km^{-2}, (1.8%) and salt marshes 3510 km^{-2}, (2.9%) (Himes-Cornell et al., 2018). In Asia, the total extent of these three ecosystems is 33224 km^{-2}, forming 27.6% of the global with highest spread of mangrove 32767 km^{-2}, which forms 28.6% of the global mangrove coverage. Area of seagrass meadows spread in Asia has been estimated as 236 km^{-2} and salt marsh 220 km^{-2},which forms 10.8% and 6.03% of the respective ecosystems globally (Himes-Cornell et al., 2018). Found at the interface between the land and the sea, seagrasses provide varied services apart from acting as ecosystem engineers providing shelter and habitat for several marine fauna which are fished in several Asian countries (Nordlund et al., 2018); (Jeyabaskaran et al., 2018); (Unsworth et al., 2019b) thereby providing livelihood to millions across the continent (UNEP, 2020).

The seagrass meadows are also good sinks of carbon (Fourqurean et al., 2012) capable of storing 19.9petagrams (Pg) organic carbon, but with very high regional and site and species variability (Ganguly et al., 2017);(Stankovic et al., 2018); (Gallagher et al., 2019); (Ricart et al., 2020). As highly efficient carbon sinks, these store up to 18 percent of the world's oceanic carbon and they also reduce the impacts of ocean acidification (UNEP, 2020).

The deterioration of this ecosystem is fast, 7% per year since 1990 (Waycott et al., 2009) which led to development of restoration protocols across Asia (Paling, 2009); (van Katwijk et al., 2016). In Vietnam, the loss of seagrass has been estimated as above 50% and in some regions complete loss has been observed (Van Luong et al., 2012). The seagrass meadows of Indonesia are fast deteriorating, and the need for increased local level autonomy for the management of marine resources and restoration have been highlighted (Unsworth et al., 2018). The need to develop science based policies for conservation including participatory methods (Fortes, 2018); (Ramesh et al., 2019) ;(Unsworth et al., 2019a), and large scale planting (van Katwijk et al., 2016) have been recommended to preserve the ecosystem services of these habitats.

Globally, the diversity of the plankton community has been predicted to be affected by warming and related changes (Ibarbalz et al., 2019) and these changes are expected in Asia also. Combined effects of high temperature, ocean acidification and high light exposure would affect important phytoplankton species in the SCS, *Thalassiosira pseudonana* (Yuan et al., 2018) and *Thalassiosira weissflogii.* (Gao et al., 2018b). Also in SCS the phytoplankton assemblage responses to rising temperature and CO2 levels were found to differ between coastal and offshore waters and the predicted increases in temperature and pCO2 may not boost surface phytoplankton primary productivity (Zhang et al., 2018).

Ocean warming and acidification can affect the functioning and ecological services of sedentary molluscs like the bivalves (Guo et al., 2016); (Zhao et al., 2017b); (Cao et al., 2018); (Zhang et al., 2019c); (Liu et al., 2020b) and gastropods(Leung et al., 2020) and also sea urchins (Zhan et al., 2020). The oyster *Crassostrea gigas* becomes more vulnerable to disease when exposed to acidification conditions and pathogen challenge indicating incapability for supporting long term viability of the population (Cao et al., 2018). More tolerance and benefits to rising pCO2 was observed in clam species like *Paphia undulate* which has been attributed to adaptation to its acidified sediment habitat (Guo et al., 2016). Warming boosted the energy budget of the marine calcifiers like the gastropod *Austrocochlea concamerata*, by faster shell growth and greater shell strength making them more mechanically resilient while acidification negatively affected the shell building thereby impacting the physiological adaptability (Leung et al., 2020). It is expected that there will be transgenerational acclimation to changes in ocean acidification in marine invertebrates (Lee et al., 2020b).

Assessment of the potential impacts and the vulnerability marine biodiversity in the Persian Gulf under climate change suggested a reduction of upto 35% of initial species richness and habitat loss for hawksbill turtles in south and southwestern parts of the Persian Gulf (Wabnitz et al., 2018).

Seaweeds are important biotic resource capable of capturing carbon and used widely as food, medicine and as raw material for industrial purposes. Warming and altered pH can affect seaweeds indifferent ways (Gao et al., 2016); (Gao et al., 2017); (Gao et al., 2018a), (Wu et al., 2019b). Outbreak of intense blooms of species like *Ulva rigida* (Gao et al., 2017) and *Ulva prolifera* (Zhang et al., 2019f) have increased due to varied factors including climate change. These have created huge economic losses in Yellow sea affecting local mariculture, tourism and the functioning of the coastal and marine ecosystems (Zhang et al., 2019f). Increased temperature was found to enhance the dark respiration (Rd) and light compensation point (EC) of *Ulva conglobate*, which thrives in the mid-intertidal to upper subtidal zones while the altered pH showed a limited effect (Li et al., 2020). Elevated temperature significantly enhanced growth, photosynthetic performances and carbon use efficiency of *Sargassum horneri* in both elevated and ambient CO2 levels suggesting that the present greenhouse effect would benefit the golden tide blooming macroalgae *Sargassum horneri*, which might enhance both the frequency and scale of golden tide (Wu et al., 2019b).

10.4.3.1 Key drivers to vulnerability

The vulnerabilities to disaster in coastal regions with high population densities are reported in several studies. (Sajjad et al., 2018) assessed the vulnerabilities of coastal community along the Chinese coast and showed that roughly 25% of the coastline and more than 5 million residents are in highly vulnerable coastal areas of mainland China, and these numbers are expected to double by 2100. Husnayaen et al. (2018) assessed along the Semarang coast in Indonesia and showed that 20% of the total coastline (48.7 km) is determined as a very high vulnerability. Mangroves continue to face threats due to pollution, conversion for aquaculture, agriculture, apart from Climate based threats like SLR and sea erosion (Richards and Friess, 2016; Romañach et al., 2018; Wang et al., 2018b) (Friess et al., 2019). Hypersalinity, storm effects sediment deposition, fishery development and land erosion are mainly responsible for most part of Sunderban mangrove degradations leading to loss of livelihood (Uddin, 2014); (Paul, 2017). In the Sunderbans of Asia, climate change is expected to increase river salinisation, which in turn could significantly negatively impact the valued timber species, *Heritiera fomes* (Dasgupta et al., 2017b). Augmented potential for honey production is also predicted which can increase man –wildlife conflict (Dasgupta et al., 2017b).

Destruction by natural hazards was found to remove the above ground C pool, but the sediment C pool was found to be maintained (Chen et al., 2018b). In Andaman & Nicobar islands the 2004 Indian Ocean Tsunami severely impacted the mangrove habitats at the Nicobar Islands (Nehru and Balasubramanian, 2018),while new inter-tidal habitats suitable for mangrove colonisation developed. Mangrove species with a wide distribution and larger propagules (showed high colonisation potential in the new habitats compared to other species (Nehru and Balasubramanian, 2018) Mangrove sites in Asia are predominantly minerogenic so continued sediment supply is essential for the long-term resilience of Asia's mangroves to SLR (Lovelock et al., 2015; Balke and Friess, 2016; Ward et al., 2016a; Ward et al., 2016b) .

10.4.3.2 Observed impacts

Primary production in Western Indian Ocean showed a reduction by 20% during the last six decades, attributed to rapid warming and ocean stratification which restricted nutrient mixing (Roxy et al., 2016) . Variation in secondary production- zooplankton densities and biomass in the East Asian Marginal Seas (EAMS) affected the recruitment of fishes due to mismatch in spawning period and larval feed availability during the last three Climate Regime Shifts (CRS) in the mid-1970s, late 1980s, and late 1990s, which were characterised by North Pacific Index (NPI) and Pacific Decadal Oscillation index (PDOI) (Kun Jung et al., 2017). In the western North Pacific Climate change has affected recruitment, and population dynamics of pelagic fishes like sardine and anchovy (Nakayama et al., 2018) and also shifts in the spawning ground and extension of spawning period in the chub mackerel *Scomber japonicas* (Kanamori et al., 2019).

Varied response to CRS Chinese Seas was observed for small pelagic (Ma et al., 2019) and Cephlalopods (Ichii et al., 2017). The winter and summer SSTs showed evidence of decadal variability with abrupt changes from cold to warm in substantial association with climate indices to which coastal cephalopods in China Seas responding differentially; some benefitting from warmer environment while others responded negatively (Pang et al., 2018). In the western and eastern North Pacific marine ecosystem it is indicated that groundfish may suffer more than pelagic fish (Yati et al., 2020) . Habitat Suitability Index models using SST, Chl-a, SSHA and SSS and fishing effort strongly indicated that Neon flying squid is affected by inter-annual environmental variations and it undertakes short term migrations to suitable habitat affecting the fisheries (Yu et al., 2015). The 2015-16 El Nino was found to impact coral reefs of shallower regions (depth of 5–15m) in South Andaman than those beyond 20 m (Majumdar et al., 2018). In the southeast coast of India, bleaching largely mediated by the SST anomaly and during the recovery period macro-algae outgrowth was observed (2.75%) indicating impacts on the benthic community (Ranith and Kripa, 2019). In South China Sea the increase in SST was found to be at a higher than the predicted in recent decade while the pH decreased at a rate of 0.012–0.014/year, more than the predicted due to high microbial respiratory processes releasing CO2 (Yuan et al., 2019). Simulation experiments showed differential adaption capacity of common species (Zheng, (2019).) (Yuan et al., 2019).

The Nations (2019) report on climate action and support trends have highlighted that the impacts of climate change on coastal ecosystems are mainly increased risks due to flooding, inundation due to extreme events, coastal erosions, ecosystem processes and on fisheries as variations in population or stock structures due to ocean circulation pattern, habitat loss degradation and ocean acidification. Analysis of data on occurrence of varied natural hazards from 1900 to 2019 (120 years) has shown that tropical cyclones, riverine floods and droughts have increased significantly and the impacts of these on coastal communities are also severe and destructive. The UNs average score for SDG Goal 14 (life under water) for Asia was estimated as 46 from scores of 40 nations and the Ocean Health Biodiversity index was comparatively high (average 87.9). However, the indices show that more region specific action plans are required to the achieve the UN 2030 goal for life under water.

Apart from the human community level impacts, the ecology and resource abundance of coastal waters have been found to be impacted by extreme events. During tropical cyclones ecological variations like lowering of SST, increase on chlorophyll a and decrease in oxygen (Chacko, 2019); (Girishkumar et al., 2019) have been observed. Global analysis on such events have indicated that these may have impact on the fishery directly by creating unfavourable ecological conditions and destruction of critical habitats indirectly by affecting the eggs and larvae and subsequent fishery recruitment (McKinnon et al., 2003); (Bailey and Secor, 2016). In South China Sea in July 2000, during a 3-day cyclone period, an estimated 30-fold increase in surface chlorophyll-a concentration was observed (Lin et al., 2003). The estimated carbon fixation resulting from this event alone is 0.8 Mt, or 2–4% of SCS's annual new production (Lin et al., 2003). Since an average of 14 cyclones pass over this region annually, the contribution of cyclones to annual new production has been estimated to be as high as 20-30% (Lin et al., 2003).

10.4.3.3 Projected impacts

Water pollution and climate stressors have been considered as major challenges to ecosystem sustainability and now it has been shown that the combined effect these two stressors would be more damaging (Buchanan et al., 2019). For seagrass beds the pollution stress was found to increase by 3.5% (from 39.7 % to 42.3%) when climate factors were added. Assuming the pollution levels to remain at 2014 levels different scenarios including RCP 2.6 and RCP 8.5 were worked out for Behoi Sea and the results indicated amplification of the impacts on ecosystem. Pollutants like Petroleum Hydrocarbons, Dissolved inorganic nitrogen and Soluble Reactive Phosphorus were the major pollution stressors (Lu et al., 2018) In the future, policies focused strictly on pollution control should be changed and should take into account the interactive effects of climate change for better forecast and management of potential ecological risks (Lu et al., 2018).

Projected changes in catch potential (%) by 2050 and 2100 relative to 2000 under RCP2.6 and RCP8.5 based on outputs from the dynamic bio-climate envelop model and the dynamic size-based food web models indicate that the marine and coastal resources of most Asian countries will be impacted with varying intensity (FAO, 2018b).

Better management of resources through projections of resource distribution, abundance and catch is required. However, lack of data (e.g., oceanographic surveys) and scientific knowledge is a constraint to this aim (Maung Saw Htoo et al., 2017). Effective forecasts of areas of resource abundance based on habitat preference have to be worked out for Asian region. Research Programs like EAF Nansen

Modelling and assessment of the vulnerability and habitat suitability of the Persian Gulf for 55 species to climate change indicated that there is a high rate of risk of local extinction in the southwestern part of the Persian Gulf, off the coast of Saudi Arabia, Qatar and the United Arab Emirates (UAE). Likelihood of reduced catch was observed and Bahrain and Iran were found to be more vulnerable to climate change(Wabnitz et al., 2018). Projected changes in fish catches can impact the supply of fish available for local consumption (i.e., food security) and exports (i.e., income generation) (Wabnitz et al., 2018). As per (UNESCAP, 2018a) Over 40 percent of coral reefs and 60 percent of coastal mangroves in the Asia-Pacific Region have already been lost, and approximately 80 percent of the region's coral reefs are currently at risk.

Regionally, the escalation in thermal stress estimated for the different global warming scenarios is greatest for Southeast Asia and least for the Pacific Ocean (Lough et al., 2018). For the 100 reef locations examined here and given current rates of warming, the 1.5 °C global warming target represents twice the thermal stress they experienced in 2016 (Lough et al., 2018).

In the southeast Asian region threats from both warming and acidification has indicated that by 2030, 99 percent of reefs will be affected and by 2050, 95 percent s are expected to be in the highest levels of threatened category (Burke et al., 2011), similar to global corals (Frieler et al., 2013), (Bruno and Valdivia, 2016) . Modelling results indicate that even under RCP scenarios the functional traits of coral reefs can be affected (van der Zande et al., 2020) and coral communities will mainly consist of small numbers of temperature-tolerant and fast-growing species (Kubicek et al., 2019). Increases in temperature (+3˚C) and pCO2 (+400 matm) projected for this century can reduce the sperm availability for fertilisation, which along with adult population decline either due to climate change or anthropogenic impacts (Hughes et al., 2017) can affect the coral reproductive success thereby reducing the recovery of populations and their adaption potential (Albright and Mason, 2013); (Hughes et al., 2018); (Jamodiong et al., 2018). In the southern Persian Gulf increased disturbance frequency and severity caused progressive reduction in coral size, cover, and population fecundity (Riegl et al., 2018), and this can lead to functional extinction. Connectivity required to avoid extinctions increased exponentially with disturbance frequency and correlation of disturbances across the metapopulation. In Philippines experiments have also proved that for Scleractinian corals like *A. tenuis, A. millepora* and *F. colemani* that spawn their gametes directly into the water column may experience limitations from sperm dilution and delays in initial sperm-egg encounters that can impact successful fertilisation (dela Cruz and Harrison, 2020).

Apart from these, threats, natural hazards have also been found to affect coral reefs of Asia. The extensive and diverse coral reefs of Muscat, Oman in the northeastern Arabian Peninsula were found to have long-term effects of Cyclone Gonu, which struck the Oman coast in June 2007 more than coastal development (Coles et al., 2015).

Sandy beaches are subject to highly dynamic hydrological and geomorphological processes, giving them more natural adaptive capacity to climate hazards (Bindoff et al., 2019). Progress is being made toward models that can reliably project beach erosion under future scenarios despite the presence of multiple confounding drivers in the coastal zone (AR6 WG2, Chap.3). Assuming minimal human intervention estimate impacts of SLR by 2100 under RCP8.5-like scenarios, 57–72% of Thai beaches (Ritphring, 2018), at least 50% loss of area on around a third of Japanese beaches (Mori, 2018) will disappear.

Marine heat waves (MHW) have been making changes in the structure and functioning of coastal and marine ecosystems (Kim and Han, 2017); (Oliver et al., 2017); (Oliver et al., 2019); (Frölicher and Laufkötter, 2018); (Smale et al., 2019) affecting resources like copepods (Doan et al., 2019) and coral reefs (Zhang et al., 2017c). in Asia. Coral reefs of Southeast Indian Ocean have been affected by marine MHW (Zhang et al., 2017c).

Simulation of RCP scenarios have shown that continued warming can drive a pole-ward shift in distribution of the seaweed Ecklonia cava of Japan and under the lowest emission scenario (RCP2.6), most population may not be impacted, but under highest emission scenario (RCP 8.5) the existing habitat may become unsuitable and it can also increase predation by herbivorous fishes (Takao et al., 2015).

10.4.3.4 Adaptation options

The Nations (2019) has identified establishment of protected areas, restoring ecosystems like mangroves / coral reefs, integrated coastal zone management practices, sand banks and structural technologies and implementing local monitoring networks for increasing adaptive capacity and protecting biodiversity of coastal ecosystem. In Asia, management of marine sites by earmarking protected areas (SDG 14) has been found to be low with only 27% area being protected. In India detailed climate change adaptation guideline coastal protection and management has been prepared considering various environmental and social aspects (Black et al., 2017). The Ocean Health Index for clean waters was also low, 54.6 and the threat to the ecosystem due to combined effect of pollution and climate change was high. Table 10.2 shows the ocean and Marine Protected Areas (MPA).

Table 10.2: Status of Ocean and MPA. Data Source: (Sachs et al., 2018)

	Ocean Health Index - Clean waters (0-100)	Fish stocks overexploited or collapsed (%)	Ocean Health Index - Fisheries (0-100)	Fish caught by trawling (%)	Ocean Health Index - Biodiversity (0-100)	Marine sites, mean protected area (%)
Eastern Asia	54.0	29.1	49.5	39.8	89.6	32.5
South-Eastern Asia	54.1	28.5	54.9	34.7	84.6	25.0
Western Asia	54.3	28.3	46.2	20.4	89.4	18.3
Southern Asia	50.3	17.4	51.0	15.1	88.3	41.2
Northern Asia	91.6	55.4	57.6	60.0	93.4	30.0
Asia	54.6	26.9	50.3	27.3	87.9	27.0

Conservation and Restoration of mangrove were found to be effective tools for enhancing ecosystem carbon storage and an important part of Reducing Emissions from Deforestation and forest Degradation plus (REDD+) schemes and climate change mitigation (Ahmed and Glaser, 2016). In East Asia restoration success has been attributed to right geomorphological locations (Van Cuong et al., 2015; Balke and Friess, 2016) and co-management models (Johnson and Iizuka, 2016; Veettil et al., 2019).

In South Asia, restoration programs have been largely successful (Jayanthi et al., 2018) but in some regions partly a failure due to inappropriate site selection, poor post planting care and other issues (Kodikara et al., 2017). Using remote sensing it was observed that there are high recovery rates of mangroves in a relatively short period of time (1.5 years) after a powerful typhoon indicating that natural recovery and regeneration would be a more economically and ecologically viable strategy. Better mangrove management through mapping is suggested (Castillo et al., 2018) (Gandhi and Jones, 2019). Statistical tools developed for modelling biomass and timber volume (Phan et al., 2019) and allometric models to estimate aboveground biomass and carbon stocks (Vinh et al., 2019) will be useful in estimating stocks in mangroves. Future mangrove loss may be offset by increasing national and international conservation initiatives that incorporate mangroves, such as the Sustainable Development Goals, Blue Carbon, and Payments for Ecosystem Services (Friess et al., 2019). Since seagrass meadows and marine macroalage are important habitats capable of combating impacts of climate change, the need for a global networking system with participation of stake holders has been suggested (Duffy et al., 2019).

10.4.4 Freshwater Resources

In Asia, freshwater resources, an important component of ecosystem services, are widely used for agriculture, domestic, irrigation, navigation, energy, industrial and ecosystem uses and services. Freshwater availability is changing at the global scale because of unsustainable use of surface and groundwater, pollution and other environmental changes. These changes in space and time, directly or indirectly, affect water use sectors and services (Wheater and Gober, 2015) (Rodell et al., 2018). About 82% of the global population served by freshwater provisions from upstream areas exposed to high threat (Green et al., 2015). Given that some of the fastest growing economies in the world today are in Asia, and the geographies of development are highly uneven, both climatic and non-climatic drivers such as socio-economic changes have contributed to water stress conditions in both water supply and demand in diverse sub-regions of Asia. In case of Asia therefore the entanglement between the non-climatic and climatic drivers makes it difficult to attribute environmental changes –both present and projected—neatly and exclusively to climatic drivers.

Immerzeel et al. (2020) has ranked all mountain-dependent water towers according to their water-supplying role and the downstream dependence of ecosystems, societies and economies. The resulting Global Water Tower Index (WTI) indicates that the upper Indus basin is both the most important and the most vulnerable Water Tower Unit (WTU) in the world. A WTU is defined as 'the intersection between major river basins and a topographic mountain classification based on elevation and surface roughness'. Whereas all important transboundary WTUs in Asia remain highly vulnerable, it is the Indus WTU (inhabited by approximately 235 million people in the basin in 2016, which is projected to increase by 50% by the middle of 21st century) where the average annual temperature is projected to increase by 1.9 °C between 2000 and 2050, with wide-ranging consequences and trans-sectoral spill overs. The Indus WTU faces a deep risk produced by a combination of factors including water stress, ineffective governance, hydro-political tensions, population growth and density, urbanisation and social transformations; with a significant bearing on SDG 6 on water, SDG 2 on food and SDG 7 on energy.

10.4.4.1 Key Drivers

Across Asia and its various sub-regions, the key drivers behind an increasingly inadequate supply of freshwater resources, affecting the livelihood security of millions, are varied, complex, and intersect with multiple social, cultural, economic and environmental stressors (Luo et al., 2017) (Tucker et al., 2015; Kongsager et al., 2016). Water stress' has been defined as the situation "when the demand for water exceeds its supply, during a certain period of time, or when poor quality restricts its use''(Felberg et al., 1999). See also Figure 4.32 in Lee et al. (2021a).

Freshwater resources in Asia, which include both surface water and groundwater, are considerably strained and changing climate is *likely* to act as a major stress multiplier (Fant et al., 2016) (Gao et al., 2018c) (Mack, 2018) (Dasgupta et al., 2015). In Southern and Eastern Asia (SEA) nearly 200 million people are at risk of serious water-stressed conditions. Effective mitigation might reduce the additional population-under-threat by 30% (60 million people), still there is a 1-in-2 chance that 100 million people across SEA might face a 50% increase in water stress and 1-in-10 chance that water stress would almost double in the absence of wide-ranging, multi-scalar adaptive measures (Gao et al., 2018c). In the absence of Millennium Development Goal 7c, that aimed to halve the population that had no sustainable access to water and basic sanitation before 2015, not been fully realised and sustainable development goals (SDG) 6 on water and sanitation not been effectively operationalised, the water-stress is *likely* to increase by the end of 2030 (Weststrate et al., 2019).

In Asia and elsewhere the interplay between the challenge of sustainability and climate change poses major policy challenges (von Stechow et al., 2016). The pursuit of SDG 6 —protection and restoration of water-related ecosystems, universal and equitable access to safe and affordable drinking water for all, improvement in water quality by reducing pollution, elimination of dumping and significant reduction in release of hazardous chemicals and materials, and treatment of wastewater through recycling and safe reuse globally—could be directly or indirectly challenged and undermined by climate change (Parkinson et al., 2019). Dissolved organic materials from sewage can enhance CO2 emission, especially in rapidly urbanising river systems which receives untreated wastewater/sewage across developing countries including Asia (Kim et al., 2019b). Conversely, policy interventions aimed at significant augmentation in water-use efficiency across all sectors, ensuring sustainable withdrawals and supply of freshwater to address water scarcity and a significant reduction in the number of victims of water scarcity, especially the poor and marginalised could mitigate vulnerabilities caused by climate change. More interdisciplinary research is needed on highly precarious future pathways and intersection between the climate and non-climate drivers in order to anticipate and mitigate diverging and uncertain outcomes.

10.4.4.2 Sub-regional Diversity

According to a quantitative scenario assessment for future water supply and demand in Asia to 2050, based on global climate change and socioeconomic scenarios (Satoh et al., 2017), water demand in sectors such as irrigation, industry, and households will increase by 30–40% around 2050 in comparison to 2010. Water stress is *likely* to be more pronounced in Pakistan, and northern parts of India and China. By mid-21st Century, the international transboundary river basins of Amu Darya, Indus, Ganges could face severe water scarcity challenges with climate change acting as a stress multiplier (*high confidence*). Within the country boundary as well, the water scarcity could be exacerbated, such as in India and China, due to various drivers like population and climate change. Research on the differentiated impact of climate change on freshwater sources across the Asian sub-regions remains inconclusive and requires assessment at sub-regional scale (IPCC, 2014b) (Wester et al., 2019).

10.4.4.3 Observed Impact

The climate change impact on different parts of freshwater ecosystems –as shown in section 10.4.2) of this chapter-- has affected water supply in various sub-regions of Asia. While headwater zones are susceptible to change in snow cover, permafrost and glaciers, the downstream plain areas of these river systems are vulnerable to increasing high demand of freshwater which will affect water availability in space and time. Observed impact of climate change has also been seen in direct physical losses such as precipitation (Mekong Delta), floods (Vietnam), salt-water intrusion leading to low agricultural productivity (Pervin et al., 2020) (Mora et al., 2018) (Almaden et al., 2019a).

The Hindu Kush-Himalaya (HKH) region extends 3500 km from Afghanistan in the west to Myanmar in the east is a source of major river systems originating in Asia, supports livelihoods, energy, agriculture and ecosystem for 240 million in the mountain and hills and 1.65 billion in the plains (Sharma et al., 2019). The HKH region stores about half of the ice mass in HMA, provisioning freshwater to almost 869 million population in the Indus, Tarim, Ganges and Brahmaputra river basins. While the warming climate increases the meltwater runoff enhancing water supply, it is indeed at the cost of glacier mass reduction that would eventually reduce meltwater and impact on the people's livelihood downstream in future (Nie et al., 2021). The melt runoff from the region play an important role in downstream agriculture such as in the case of Indus where two thirds of total irrigation withdrawal is from melt runoff in the pre-monsoon season (Biemans et al., 2019). Changes in cryosphere and other environmental changes have already impacted people living in high mountain areas and are *likely* to introduce new challenges for water, energy, and food security in the future (Rasul and Molden, 2019) (Borodavko et al., 2018; Adler et al., 2019; Bolch, 2019; Hoelzle et al., 2019; Shen et al., 2020).

With climate change impacts resulting in the shrinking and melting of snow, ice, glacier, and permafrost, and correspondingly causing increase in meltwater, the incidences of flash floods, debris flow, landslides, snow avalanches, livestock diseases, and other disasters in the HKH region have become more frequent and intense. Some of the key factors that come in the way of assigning confidence levels to climate change impacts include lack of sufficient observed data on factors such as river discharges, precipitation and glacier melt (You et al., 2017). Climate change impacts on cryospheric water sources in the Hindu Kush, Karakoram and Himalayan ranges which in turn carry consequences for the Indus, Ganges and Brahmaputra basins.

The combined impacts of climate change and non-climate drivers on hydrological processes and water resources in transboundary rivers in diverse regions of Asia were well noted in AR5. In Central Asia withdrawal is approximately equal to water availability, with Turkmenistan and Uzbekistan as most water stressed countries in the region (Karthe et al., 2017); (Russell, 2018). A study on water availability in mainland South Asia has pointed in the direction of decreasing precipitation trends in recent years, which have also contributed to the increasing incidence and severity of droughts (Liu et al., 2018b). There are reports of increase in occurrence and severity of different forms of droughts in the Koshi river basin (Central Himalaya) (Wu et al., 2019a; Hamal et al., 2020; Dahal et al., 2021; Nepal et al., 2021). Figure 10.5 shows the water stress in the HKH region. The water stress is relatively higher in western region compared to central and eastern region.

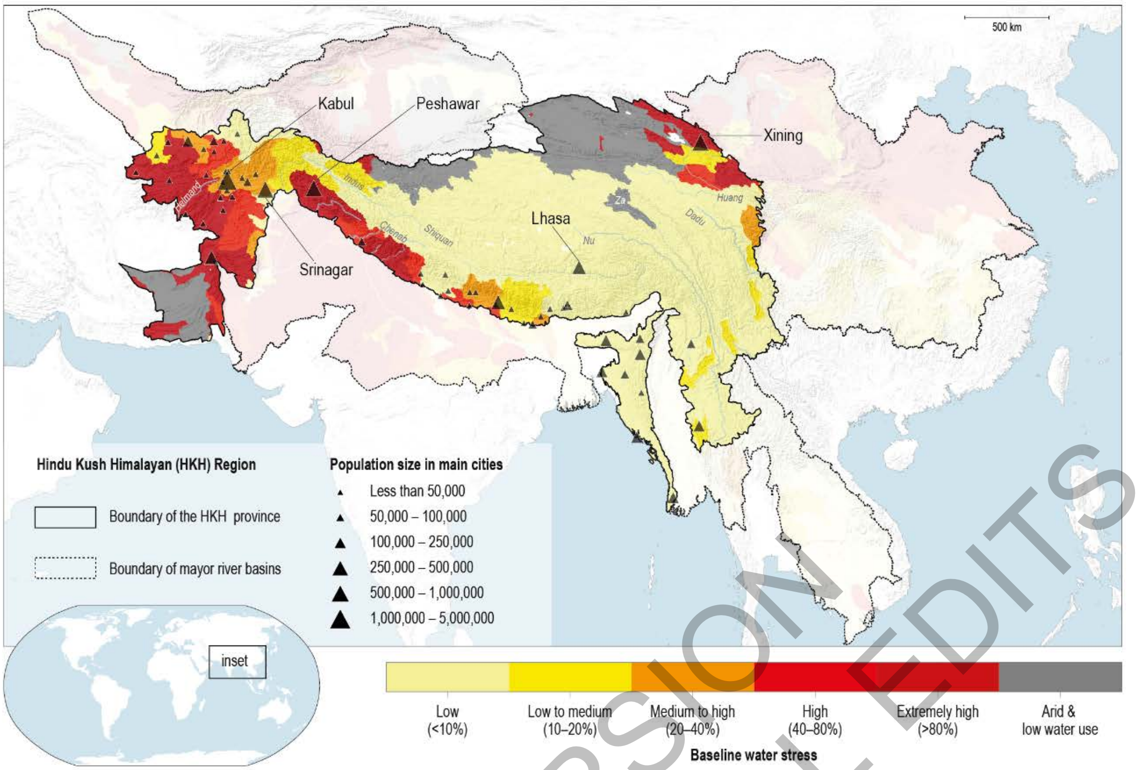

Figure 10.5: Water Stress in the Hindu Kush-Himalaya (HKH) region Source: (Wester et al., 2019). *The Hindu Kush Himalaya assessment: mountains, climate change, sustainability and people* (p. 627). Springer Nature; (Hu and Tan, 2018). No water, no growth – Does Asia have enough water to develop? China Water Risk. **Note:** The map is for illustrative purpose only. The boundaries and names shown and the designations used on this map are for river basins and do not imply official endorsement or acceptance by the United Nations.

Climate change is also having an impact on stream flows. A recent study (Chen et al., 2018f) has shown that with the average temperature after 1998 being 1.0°C higher than that during 1960–1998 in the Tienshan Mountains, the process of glacier shrinkage and decreases in snow cover and causing earlier runoff peak and aggravated extreme hydrological events, affecting regional water availability and adding to future water crisis in Central Asia. The magnitude and frequency of flooding have increased across Himalayan region in the past six decades such as Tarim basin in China (Zhang et al., 2016c) and higher Indus, Ganges and Brahmaputra (Elalem and Pal, 2015). The latter also reported the highest number of flood disaster and greater spatial coverage in the recent decades as compared to earlier decades. In the Middle Yellow River Basin, which has become much warmer and drier, climate variability accounts for 75.8% of streamflow decrease during 1980–2000. Whereas during 2001–2016, land use/cover change is the main factor in streamflow decrease, accounting for 75.5% of the decline (Bao et al., 2019). The changes in hydrological regime and extreme floods cause changes in the river morphology and river channel system which impact water availability.

In China, a quantitative assessment based on a multimodel dataset (6 global hydrological models driven by 3 observation-based global forcings) during the 1971-2010 period, suggested that climate variability dominated the changes in streamflow in more the 80% of river segment, while direct human impact dominated changes mostly in northern China (Liu et al., 2019b). In the Lancang-Mekong River basin, climate variability would have contributed 45% more flood occurrences in the middle of the basin while reservoir operation reduced it by 36% during 2008-2016 compared to the period 1985-2007 (Yun et al., 2020).

In western China, the total annual snow mass declines at a rate of 3.3 × 109 Pg per decade ($p < 0.05$), which accounts for approximately 0.46% of the mean of annual snow mass (7.2 × 1011 Pg). The loss could be valued in terms of replacement cost at CN¥0.1 billion (in the present value) every year ($1 = CN¥7) in the past 40 years. Compounded (Wu et al., 2021). In the Mekong River Delta in Vietnam, climate change impacts include a 30% annual increase in rainfall, shifting rainfall patterns, an average temperature increase of 0.5°C over the last 30 years, and an average sea level rise of 3mm per year over the last three decades, resulting in a greater flooding threat (Wang et al., 2021a).

A recent study (Wang et al., 2021b) has shown that during 1936–2019, due largely to intensified precipitation induced by a warming climate , the streamflow of Ob, Yenisei and Lena has increased by ~7.7%, 7.4% and 22.0%, respectively. Whilst rising temperature can reduce streamflow via evapotranspiration, it can enhance groundwater discharge to rivers due to permafrost thawing. In permafrost-developed basins, the thawing permafrost will continue to result in increased streamflow. However, with further permafrost degradation in future, the positive effect of permafrost thaw on streamflow would probably be offset by the negative effect of increase in basin evapotranspiration. This could result in a situation where runoff reaches threshold level and then declines. This is clearly marked in the Ob River basin, which is characterised by the highest precipitation. Whereas in case of Yenisei and Lena rivers, further research is needed.

The HKH region is susceptible to floods and related hazards caused by a cloud burst and other landscape-based processes such as glacial lake outburst floods which can seriously damage property, lives and infrastructure (Shrestha et al., 2010). Himalayan rivers are frequently hit by catastrophic floods caused by the failure of glacial lake (Cook et al., 2018) (Ahluwalia et al., 2016). In Kedarnath, India (western Himalaya), a flash flood was triggered by GLOF released from the Chorabari glacial lake in June 2013 which caused extensive flooding, erosion of riverbanks and damage to downstream villages and towns, as well as the loss of several thousand human lives in the state of Uttarakhand (Rafiq et al., 2019); (Das et al., 2015). Nepal has experienced 24 GLOF events which have caused considerable loss of life and damage to properties and infrastructure (Icimod, 2011). There is *high confidence* that current glacier shrinkages have caused more glacial lakes to form in most of the mountainous region including High mountain Asia but limited evidence that the frequency of GLOF has changed (Hock et al., 2019). (Veh et al., 2018) reported no clear trend of increasing GLOF events in the Himalayan region, although southern Himalaya was identified as a hotspot region compared to western Himalaya. Research has shown a decrease in glacier area of 24% in Nepal between 1980 and 2010 (Bajracharya et al., 2014).

Climate change impacts on both the quantity and quality of freshwater resources will hinder the attainment of SDG-6 (Water, 2020). Contamination of drinking water is caused by wildfires and drought that contribute to elevated levels of nutrients (nitrogen, phosphorus and sulphates), heavy metals (lead, mercury, cadmium and chromium), salts (chloride and fluorides), hydrocarbons, pesticides and even pharmaceuticals. Heavy rains and flooding also increase nutrients, heavy metals and pesticides as well as turbidity and fecal pathogens in water supplies - especially when sewage treatment plants are overwhelmed by runoff (Mora et al., 2018). Pharmaceuticals and personal care products (from source to disposal) are contributing to the vulnerability of urban waters. A study of vulnerability assessment of urban waters in highly populated cities in India and Sri Lanka, through analysing the concurrence of PPCPs, enteric viruses, antibiotic resistant bacteria, metals,
fecal contamination, and ARGs, also underlines the need for a resilience strategy and action plan (Rafiq et al., 2019).

Adequate water supply for various uses is crucial for millions of people living in the mountains of Asia. Particularly in the HKH region, mountain springs play an important role in generating stream flow for non-glaciated catchments and in maintaining dry-season flows across many watersheds (Scott et al., 2019) (Stott and Huq, 2014). There is a good deal of evidence that the springs are drying up or yielding less discharge (Tambe et al., 2012), (Tiwari and Joshi, 2014) (Sharma et al., 2016), threatening local communities who depend on spring water for their lives and livelihoods. Some of the main reasons for drying springs include anthropogenic impacts (deforestation, exploitative land use), infrastructure (road construction), socio-economic changes (increasing demand and modernisation of facilities) and climatic changes (changes in rainfall regime and higher temperature) (Stott and Huq, 2014; Tiwari and Joshi, 2014; Sharma et al., 2016).

The Ganges-Brahmaputra region also faces the threat increased frequency of flood events (Lutz et al., 2019). Floods and extreme events can impact river channel systems (Grainger and Conway, 2014). One of the challenges in South Asia is the shifting boundaries of river channels. For instance, the major floods on the

Indus in July 2010 altered the river's course in Pakistan, moving it closer to the Indian district of Kutch (Grainger and Conway, 2014). In the eastern tributary of Ganges system, the alluvial fan of the Koshi river basin has shifted to more than 113 km to the west in past two centuries (Chakraborty et al., 2010) which may be due to heavy sediment load from the Himalayan rivers in which about 50 million tons of sediment is deposited annually in the alluvial plains (Sinha et al., 2019) (Chakraborty et al., 2010).

Asia is no exception to the global trend of lake ecosystems providing drinking water to millions of people, being degraded (Jenny et al., 2020) and severely threatened at the same time by climate change (Mischke, 2020), with lake surface conditions, such as ice cover, surface temperature, evaporation and water level, responding dramatically to this threat, and carrying implications for water quantity and quality, food provisioning, recreational opportunities and transportation (Woolway et al., 2020). Due to substantial regional variability, the quantum of future changes in lake water storage remains uncertain. A recent study (Liu et al., 2019a) using Moderate Resolution Imaging Spectroradiometer (MODIS) 500m spatial resolution global water product data, and applying Least Squares Method (LSM) to analyse changes in the area of 14 lakes in Central Asia from 2001 to 2016, has shown that the shrinking of area changes for all plains lakes in the study region could be attributed to climate change and human activities.

10.4.4.4 Projections

Asian and global water demands for irrigation, despite geographical variation in terms of water availability, are *very likely* to be surpassing supply by 2050 (Chartres, 2014). A regional quantitative assessment (Lutz et al., 2019) of the impacts of a 1.5 versus a 2 °C global warming for a major global climate change hotspot: the Indus, Ganges, and Brahmaputra river basins (IGB) in South Asia, shows adverse impacts of climate change on agricultural production, hydropower production, and human health. A global temperature increase of 1.5 °C with respect to pre-industrial levels would imply a ≈ 2.1 °C temperature increase for IGB. Whereas under a 2.0 °C global temperature increase scenario, these river basins would warm up by ≈ 2.7 °C. Future warming is expected to further increase rain-on-snow (ROS) events that can cause the snowmelt flood during winter (Ohba and Kawase, 2020), affecting hydropower and resulting in river flooding, avalanches and landslides.

In the Mekong River Delta (in Vietnam) with an area of 40,500 km2 and the home to 17.8 million people in 2018, climate change is projected to increase the average temperature by 1.1-3.6 ◦C, and the maximum and minimum monthly flow are projected to increase and decrease, respectively, and *likely* to result in a high risk of food during the wet season and water shortages during the dry season (Wang et al., 2021a).

In High Mountain Asia, the glacier ice is projected to decrease by 49 ± 7 % and 64 ± 5% by the end of the century under RCP 4.5 and 8.5 scenarios (Kraaijenbrink et al., 2017). Local and regional-scale projections suggest that peak water will generally be reached around middle of the century, followed by steadily declining glacier runoff thereafter (Hock et al., 2019). A global-scale projection suggests that decline in glacier runoff by 2100 (RCP8.5) may reduce basin runoff by about 10% at least one month of the melt season in High Mountain Asia (Huss and Hock, 2018). Significantly, research on climate change and its impact across Asia remains inconclusive and requires an assessment at sub-regional scale (IPCC, 2014a); (Wester et al., 2019).

There is a projection of an increase in runoff until the 2050s mainly due to an increase in precipitation in the upper Ganges, Brahmaputra, Salween and Mekong basins, where it could be due to accelerated melting in the upper Indus basin. The runoff could increase in the range of 3-27% (7-12% in Indus, 10-27% in Ganges and 3-8% in Brahmaputra) by mid-century compared to the reference period (1998-2008) for Himalayan river basins depends on different RCP scenarios (Lutz et al., 2014a). Likewise, Khanal et al. (2021) suggested contrasting responses of climate change for HMAs rivers in which at the seasonal scale, the earlier onset of melting causes a shift in magnitude and peak of water availability whereas an annual scale, total water availability increases for the headwaters. The future flow would increase in the Central Himalaya region in Nepal (Ragettli et al., 2016); (Nepal, 2016); (Bajracharya et al., 2018). These changes in water availability in space and time will have serious consequences in downstream water availability for various sectoral uses and ecosystem functioning in Asia (Green et al., 2015) (Wijngaard et al., 2018); (Nepal et al., 2014); (Rasul and Molden, 2019) (Arfanuzzaman, 2018). However, future water availability has large uncertainty due to large variation in climate change projections among different global climate models (Nepal and Shrestha, 2015; Lutz et al., 2016; Li et al., 2019a).

A recent study (Didovets et al., 2021), covering eight river catchments having diverse natural conditions within Central Asia, where water availability/scarcity is also a major developmental concern, and using the eco-hydrological model SWIM (including scenarios from five bias-corrected GCMs under Representative Concentration Pathways 4.5 and 8.5) has show an increase of mean annual temperature in all catchments for both RCPs to the end of the 21st century. The projected changes in annual precipitation indicate a clear trend to increase in the Zhabay and to decrease in the Murghab catchments, and for other catchments, they were smaller. Both the projected trends for river discharge and precipitation show an increase in the northern and decrease in the southern parts of the study region. Whereas seasonal changes include a shift in the peak of river discharge up to one month, shortage of snow accumulation period, and reduction of discharge in summer months.

The intensity and frequency of extreme discharges are *very likely* to increase towards the end of the century. The future of the upper Indus basin water availability is highly uncertain in the long run due to uncertainty surrounding precipitation projections (Lutz et al., 2016). The future hydrological extremes of the Upper Indus, Ganges and Brahmaputra river basins suggest an increase in the magnitude of extremes towards the end of the 21st century by applying RCP4.5 and 8.5 scenarios, mainly due to increase in precipitation extremes (Wijngaard et al., 2017). In the Brahmaputra, Ganges and Meghna including the downstream component, the runoff is projected to increase by 16%, 33% and 40% respectively under the climate change scenarios by the end of the century in which the changes in runoff are larger in the wet seasons than the dry season (Masood et al., 2015). In the Mekong river basin also, extremely high flow events are *likely* to increase in both magnitude and frequency which can exacerbate flood risk in the basin (Hoang et al., 2016). However, the uncertainty is high in the future hydrological response due to large variation in precipitation projections, modelling approaches and bias corrections methods (Nepal and Shrestha, 2015; Lutz et al., 2016; Li et al., 2019a).

Current research on adverse relationship between climate change and river flows, research suggests that there is high possibility that some of the river basins affected by floods could be Brahmaputra, Congo, Ganges, Lena, Mekong, with a return period of 10 years (Best, 2018).

In most parts of the Upper Ganges and Brahmaputra rivers, the 50-year return level flood is *likely* to increase and to a lesser degree in Indus river. Similarly, the extreme precipitation events are also expected to increase to a higher degree in Indus than Ganges and Brahmaputra basins (Wijngaard et al., 2017). Increase in extreme precipitation events is *likely* to cause more flash flood events in the future (*medium confidence*). In case of Indus, increasing temperature trend in the future may lead to accelerated snow and ice melting which may increase the frequency and intensity of floods in the downstream areas (Hayat et al., 2019). The Ganges-Brahmaputra region also faces the threat of increased frequency of flood events (Lutz et al., 2019).Additionally, the Ganges basin also shows a higher sensitivity to changes in temperature and precipitation (Mishra and Lilhare, 2016).

Assessing the impact of climate change on water resources in nine alpine catchments in arid and semi-arid Xinjiang of China (Li et al., 2019a), it has been noted that even though the total discharge revealed an overall increasing trend in the near future, the impact of climate change on different hydrological components indicated significant spatiotemporal heterogeneity in terms of the area, elevation and slope of catchments, which could be usefully factored into climate adaptation strategies.

It was noted early on (Singh et al., 2011), that the main drivers that influence the provisioning of ecosystem services and human wellbeing in the HKH region are a mix of environmental change in general and climate change in particular, and much more data and knowledge a on the HKH region are needed in order to develop either a regional or global understanding of climate change processes.

Climate change impacts cryospheric water sources in the Hindu Kush, Karakoram and Himalayan ranges which in turn carry consequences for the Indus, Ganges and Brahmaputra basins. The impact of climate change on spring fed rivers in the Hindu Kush-Himalayas is under-researched and therefore make projections difficult. Further research is needed for understanding the impact of deforestation, urbanisation, development and introduction of water infrastructures such as tube-wells in the hill region (Aayog, 2017). This in turn call for greater investment in R&D for the Hindu Kush-Himalayas by both the national and regional organisations. There is *high confidence* that due to global warming Asian countries could experience increase of drought conditions (5-20%) by the end of this century (Prudhomme et al., 2014; Satoh et al., 2017).

Soil erosion in high mountains areas is particularly sensitive to climate change. A recent study (Wang et al., 2020) focused on the mid-Yarlung Tsangpo River, located in the southern part of the Tibetan Plateau, has revealed dramatic land surface environment changes due to climate change during the last decades. It has further shown that increasing precipitation and temperature would lead to increasing soil erosion risk in ~ 2050 based on the Coupled Model Intercomparison Project (CMIP5) and RUSLE models.

High-resolution climate change simulations suggest that due to deadly heat waves projected in some of the densely populated agricultural regions of South Asia (i.e. Ganges and Indus river basins), are *likely* to exceed the critical threshold of wet-bulb temperature of 35 °C under the business-as-usual scenario of future greenhouse gas emissions (Im et al., 2017).

[START BOX 10.4 HERE]

Box 10.4: Cryosphere

Asia's glaciers are in minor area shrinkage and mass loss among other world's glacierised regions during 2006-2016, resulting in near minimal contribution to sea level rise (1-7 Gt/a) (Zemp et al., 2019) (*high confidence*). However, Asia's glaciers are regarded as a reliable water source (Bolch, 2017). The melting water from Asia's glaciers protect ca. 220 million people in local and adjacent regions from drought, and the closer a region to river sources, the higher the fractions of melt water from glaciers (Pritchard, 2019). Researchers have found that the southern Tibetan Plateau has been consistently melting from 1998-2007 and is projected to continue melting until 2050 (Lutz et al., 2014b) (*high confidence*). The changes in snowmelt water can explain 19% of the variations in rivers of arid regions like Xinjiang, China (Bai et al., 2018) (*medium confidence*), and the 10.6% of the runoff of the upper Brahmaputra River was contributed by snow during 2003-2014 (Chen et al., 2017c) (*medium confidence*). The dominances of snow melt in spring were found in major river basins originating from southern Tibetan Plateau, compared to the glacier melt in summer (Lutz et al., 2014b).

On the other hand, the decreased stability of Asian glaciers, caused by warming climate (Ding et al., 2019) has posed a number of threats to regional security and water supplies (Gao et al., 2019). The *likely* increased frequency of hazards caused by abnormal glacier changes, such as the glacier collapses happened on two glaciers in western Tibet in 2016 (Kääb et al., 2018), and also surges which were frequently found in this vast region (e.g. Bhambri et al., 2017; Mukherjee et al., 2017; Ding et al., 2018), threatening the security of the local and down streaming societies (*high confidence*). However, the influence of climate change on natural hazards from glaciers needs further research.

The expansion of glacier lakes, following the shrinking glaciers, has also posed threat to social security downstream through glacier lake outburst flood (GLOF). The total amount and area of glacier lakes increased during last decade according to new studies (Zhang et al., 2015; Chen et al., 2017c) (*high confidence*). New GLOF events were continuously appearing all over Asia (e.g. Allen et al., 2016; Haeberli et al., 2016; Gurung et al., 2017). However, the frequency of GLOF has remained unchanged since later 1980s (Veh et al., 2019) (*high confidence*).

The impacts of permafrost changes on regional hydrology in Asia remains unclear. However, those changes may alter the soil carbon storage (e.g. Nie et al., 2019) and increase the riverine carbon exports (e.g. Song et al., 2019). But the fate of soil carbon within permafrost is more complicated and uncertain due to the influences of heterogeneous landforms, as pointed out in China's Second National Soil Survey (Jiang et al., 2019).

[END BOX 10.4 HERE]

10.4.4.5 Climate Vulnerability and Adaptation: Interfaces and Interventions

In Asia and its diverse sub-regions, the challenge of adaptation to climate change at diverse sectors, sites and scales of vulnerability in the domain of fresh water resources is compounded by the nexus between long-standing non-climatic vulnerabilities and climatic impacts, both observed and projected. Water insecurities in Asia are increasing due to excessive freshwater withdrawals (Satoh et al., 2017) economic and population growth (Gleick and Iceland, 2018), urbanisation and peri urbanisation (Roth et al., 2019) food insecurity (Demin, 2014) and lack of access to clean and safe drinking water (Cullet, 2016) which mostly affects the heath of most vulnerable sections of society.

Significantly, climate change will add to already existing vulnerabilities. In the case of Yellow River basin in China, underlining the interface between the future water scarcity and hydroclimatic and anthropogenic drivers, a recent study expects moderate to severe water scarcity over six Yellow River sub-catchments under the RCP4.5 scenario, and anticipates that human influences on water scarcity will be worse than that of climate change, with water availability in the downstream being impacted by concurrent changes in land-use and high temperature (Omer et al., 2020). Nearly 8% of internationally shared or transboundary aquifers (TBAs), ensuring livelihood security for millions of people through sustaining drinking water supply and food production, are currently overstressed due to human overexploitation (Wada and Heinrich, 2013). The Asia Pacific region has the highest annual water withdrawal due to its geographic size, growing population and irrigation practices, and water for agriculture continues to consume 80% of the region's resources (Taniguchi et al., 2017b; Visvanathan, 2018).

In South Asia, surface and groundwater resources are already under stress (both in terms of quality and quantity) due to population growth, economic development, poor governance/management and poor efficiency of use in economic production. In the last 40 years, there has been an increasing reliance on groundwater in South Asia for irrigation (Rodell et al., 2009; Surie and Prasai, 2015; Shah et al., 2018) (Tiwari et al., 2009) (Bhanja et al., 2016) (Shrestha et al., 2016; Mukherjee, 2018). It is significant to note that India, Bangladesh, Pakistan, and China together account for more than 50% of the world's groundwater withdrawals (Scott et al., 2019). A study conducted in Shahpur and Maner district of Bihar, India in which drinking water sourced from groundwater of 388 households was tested, shows that 70 to 90 percent of the sampled household's drinking water contained either arsenic or iron or both (Thakur and Gupta, 2019). Given the nexus between climatic and non-climatic drivers, an effective adaptation to the impacts of climate change would also demand sustainable development and management of shared aquifer resources, which in turn require reliable TBA inventories and improved knowledge production and knowledge sharing on the shared groundwater systems (Lee et al., 2018a).

In a study of peri-urban spaces, involving four South-Asian cities: Khulna (Bangladesh) (Pervin et al., 2020), Gurugram and Hyderabad (India), and Kathmandu (Nepal), shows nexus between intensifying use and deteriorating quality of water and the impact of climate change, resulting in peri-urban water insecurity and conflict (Roth et al., 2019). The challenge of ensuring access to water resources and their (re) allocation and prioritisation for marginalised communities remains on the agenda of policy-oriented interdisciplinary research and demands effective implementation of its findings at the grass root level by the administrative agencies. Taking water security as a key climate change adaptation goal at the urban-city-scale of Bangkok, a study (Babel et al., 2020) has shown the usefulness of a generic framework with 5 dimensions, 12 indicators, and a set of potential variables to support national level initiatives and plans in diverse climatic and socio-economic conditions across various sub-regions of Asia.

In the Kathmandu valley in Nepal, where groundwater resources are under immense pressure from multiple stresses, including over-extraction and climate change, mapping groundwater resilience to climate change has been demonstrated as a useful tool to understand the dynamics of groundwater systems, and thereby facilitating the development of strategies for sustainable groundwater management (Shrestha et al., 2020).

In Mekong Delta, the groundwater storage in Mekong Delta is projected to decline by more than 120 and 160 million cubic meter under RCP4.5 and RCP8.5 scenarios, respectively, by the end of the 21st century, in conjunction with land subsidence and sea level rise. This in turn calls for proactive planning and implementation of adaptation strategies that address multiple stresses in order to ensure sustainable utilisation of groundwater resources in the Mekong Delta in the context of future climatic conditions and associated uncertainties (Wang et al., 2021a). Proposed climate change adaptation strategies for the Mekong River Basin include a better understanding of the complex linkages between climate change, technological interventions, land use change, water use change, and socioeconomic developments both in the upstream and downstream riparian countries (Evers and Pathirana, 2018).

While South Asian countries have done well in attaining Goal 6 of Sustaining Development Goals, access to safe and clean drinking water remains a challenge. Taking Indian rivers as an example, it is suggested that participatory river protection and rehabilitation, based on comprehensive knowledge of the river-system dynamics, and local awareness at community level may act as a multiplier for river conservation measures (Nandi et al., 2016).

[START BOX 10.5 HERE]

Box 10.5: Case Study: Climate Vulnerability and Cross Boundary Adaptation in Central Asia

In Central Asia, water has been ranked in the top five global risks and water scarcity (Gleick, 1993; Zhupankhan et al., 2018). Cross boundary adaptation remains critically important in this region with abundant glaciers in Pamir Plateau of Tajikistan (Hu et al., 2017) and areas with severe glacier retreat in Tianshan Mountains (Liu and Liu, 2015). The spatial variations of glacier and other climate variables have added to uncertainty related to the dynamic of water cycle. The headwater regions, such as Pamir area, would be significantly affected by the climate parameters, such as the stronger rainfall intensity, more frequent rainfall and higher temperature (Luo et al., 2019). The water resources in Pamir plateau will range from-0.48% to 5.6% (Gulakhmadov et al., 2020), and the crop phenological period in Tajikistan and Kyrgyzstan will be about 1-2 weeks earlier. The threat of agricultural water stress is increasing as well. The oasis in downstream areas will face more complex water resource fluctuations, water crisis and desertification. In particular, rain fed agriculture in Northern Kazakhstan, Uzbekistan and Western Turkmenistan, is particularly dependent on water resources. Under RCP2.6 and RCP4.5 scenarios, considering CO_2 fertilisation effects and land use projections, the increase of CO_2 atmospheric concentration and accumulated temperature can contribute to 23% increase of cotton yield in Central Asia (Tian and Zhang, 2019), but extreme climate such as drought, heat waves and rainstorm will have 10% negative impact on agricultural production and ecological environment (Zhang and Ren, 2017). High efficiency water-saving technology will help the upstream and downstream water resources management in Central Asian countries to adapt to the variation in water resources quantity, frequency and spatial pattern.

[END BOX 10.5 HERE]

Hydro-climatic extreme in the HKH region could adversely impact the Ganga, Brahmaputra and Meghna Basins (Wijngaard et al., 2017; Acharya and Prakash, 2019). On adaptation, studies have recommended watershed or basin analysis to address the challenge of adaptation in urban spaces (Lele et al., 2018). A study of Northern Bangladesh, focused on encouraging traditional ways of cultivation, suggests that rural women have Indigenous Knowledge and their participation can play a useful role (Kanak Pervez et al., 2015). The knowledge pertains to agriculture, soil conservation, fish and animal production, irrigation and water conservation. There has also been a focus on gendered construction of local flood forecasting knowledge of rural communities in India living in the Gandak River basin (Acharya and Prakash, 2019). While designing the adaptation options, understanding Water-Energy-Food (WEF) nexus among different water use sectors are crucial (See **10.5.3.** for details). The understanding of WEF nexus could be beneficial for achieving water security in developing countries in Asia (Nepal et al., 2019).

AR5 had identified a number of adaptation challenges and options facing the stakeholders in the wake of climate change-induced vulnerabilities, uncertainties and risks in the freshwater sector, and underlined the importance of an integrated management approach, acknowledging diverse socio-economic contexts, differentiated capacities and uneven pace of impacts. Further validated by recent research in terms of their usefulness, these adaptation options include building and improving capital intensive physical water infrastructure such as irrigation channels, flood control dams and water storage (Nüsser and Schmidt, 2017). Drawing upon customary institutions and combining Indigenous Knowledge systems with scientific knowledge, innovative structures, including artificial glaciers, ice stupas and snow barrier bands, have been built by local communities in Ladakh and Zanskar and Himachal Pradesh in India (Hock et al., 2019). (Nüsser et al., 2019). Communities in Solukhumbu, Nepal, in response to depleting water flow in snow-fed rivers, have chosen adaptation through changing practices by collecting water from distance sources for domestic consumption (McDowell et al., 2013). Taking IPCC concept of climate risk as a basis for adaptation planning a pilot study of flood risk in Himachal Pradesh, India (Allen et al., 2018), integrating assessment of hazard, vulnerability and exposure in the complementary domains of climate change adaptation and disaster risk reduction, identifies stakeholder consultation, knowledge exchange and institutional capacity building as key steps in adaptation planning. Aquifer Storage and Recovery (ASR) has been proposed as an 'alternative climate-proof freshwater source' for deltaic regions in Asia, particularly those with a history of saline groundwater aquifers (Hoque et al., 2016). It is further argued (Hadwen et al., 2015) that water, sanitation and hygiene (WASH) objectives would need to be addressed as a component of a wider integrated water resource management (IWRM) framework.

Ensuring sustainability of the rivers and eco-systems requires coordinated and collaborative action on part of all countries with the long-term goal of synergising political, social, cultural and ecological facets associated with the riverine system. Daunting as this challenge is, evidence suggests that a long term view of transboundary basins, is not very optimistic as big rivers of Asia contribute heavily towards urban and agricultural activities, and are witnessing challenges of increasing sedimentation, large scale damming and pollution amongst others (Best, 2018). In case of China, Sun et al. (2016) show that the localised vulnerabilities within the Yangtze River Basin prompt an 'integrated basin-wide approach' that is able to account for the specific needs of each of its sub-basins.

In high mountain areas, factors that undermine effective adaptation to climate change include both the sudden-onset and slow-paced disasters and knowledge deficit about cryospheric change and its adverse impacts on water resources, agriculture, and hydropower sectors. Other key barriers include sectoral approach, overemphasis on structural approaches, the lack of context-sensitive, community-centric understanding of how these changes influence perceptions, options, and decisions about migration, relocation, and resettlement (Rasul et al., 2020) (Hock et al., 2019). More interdisciplinary research is needed on highly precarious future pathways and intersection between the climate and non-climate drivers in order to anticipate and mitigate diverging and uncertain outcomes.

10.4.5 Agriculture and Food

Asia accounts for 67% of the global agricultural production (Mendelsohn, 2014) and employs a large portion of the population in many developing member (Briones and Felipe, 2013; ADB, 2017b; ILO, 2017a). Since the release of IPCC AR5, more studies reinforce the earlier findings on the spatial and temporal diversity of climate change impacts on food production in Asia depending on the geographic location, agroecology, and crops grown (Hoegh-Guldberg et al., 2018; Ahmad et al., 2019), recognising that there are winners and losers associated with the changing climate across scales (Dasgupta et al., 2013a; Yong-Jian et al., 2013; Bobojonov and Aw-Hassan, 2014; Hijioka et al., 2014; Li et al., 2014a; Prabnakorn et al., 2018; Trisurat et al., 2018; Matsumoto, 2019). Despite the observed increase in total food production in terms of crops and food yields from 1990 to 2014 in Asia (FAO, 2015), there is *high confidence* that overall, at the regional level, the projected total negative impacts will far outweigh the expected benefits with India emerging as the most vulnerable nation in terms of crop production (Figure 10.6). Recent evidence also indicates that climate-related risks to agriculture and food security in Asia will progressively escalate as global warming reaches 1.5°C and higher above pre-industrial levels (IPCC, 2018b) with differentiated impacts across the Asian continent.

10.4.5.1 Observed Impacts

There remains a paucity of data for observed climate change impacts on Asian agriculture and food systems since the release of IPCC AR5. Most of these impacts have been associated with drought, monsoon rain, and oceanic oscillations, the frequency and severity of which have been linked with the changing climate (Heino et al., 2018; Heino et al., 2020). In general, major impacts to agricultural production such as those observed by the farmers in the Philippines and Indonesia include among others delays in crop harvesting, declining crop yields and quality of produce, increasing incidence of pests and diseases, stunted growth, livestock mortality, and low farm income (Stevenson et al., 2013). In South Asia, the series of monsoon floods from 2005 to 2015 contributed to high level of loss in agricultural production with peaks in 2008 and 2015 (FAO, 2018a). Similarly, in Pakistan, farmers are experiencing decline in crop yields and increasing incidence of crop diseases as a result of climate extremes particularly floods, droughts and heat waves (Fahad and Wang, 2018; Ahmad et al., 2019).

Limited studies have quantified the actual impacts of climate change on agricultural productivity and the economy. In a study in Mun River Basin, Northeast Thailand, yield losses of rice due to past climate trends covering the period of 1984–2013 was determined to be in the range of < 50kg/ha per decade or 3% of actual average yields with high possibility of more serious yield losses in the future (Prabnakorn et al., 2018). Likewise, in China, an economic loss of $595-858 million for the corn and soybean sectors was computed from 2000 to 2009 (Chen et al., 2016b). On the other hand, the intensive wheat-maize system in China seems to have benefited from climate change with the northward expansion of the northern limits of maize, and multi-cropping systems brought about by the rising temperature (Li and Li, 2014).

There is *high agreement* in more recent studies that linked the frequency and extent of El Niño phenomenon with global warming (Thirumalai et al., 2017; Wang et al., 2017a; Hoegh-Guldberg et al., 2018) that can trigger substantial loss in crop and fishery production. The 2004 El Niño caused the Philippines an 18% production loss during the dry season and 32% production loss during the wet season (Cruz et al., 2017). In the 2015 El Nino event, the Indian oil sardine fishery declined by more than 50% of the previous years (Kripa et al., 2018) severely impacting the coastal livelihood and economies (Shyam et al., 2017). The 2015-2016 El Niño also inflicted adverse impacts in agricultural productivity and food security, especially affecting the rural poor in middle- and lower-income countries in Southeast and South Asia (UNDP ESCAP OCHA RIMES APCC, 2017).

10.4.5.2 Projected Impacts

10.4.5.2.1 Fisheries and aquaculture

The fisheries and aquaculture production from Asia in 2019 was estimated at 159.67 mmt contributing to 74.7% of the global production (FAO, 2020). This sector provides employment to an estimated 50.46 million people where fishing and aquaculture are important socio-economic activities and fish products are a substantial source of animal protein (Bogard et al., 2015; Azad, 2017; FAO, 2018c). The economic contribution could be as high as 44 % of the coastal communities' GDP as in the case of Sri Lanka (Sarathchandra et al., 2018). Five Asian countries (i.e., China, Indonesia, India, Vietnam, Japan) are in the top 10 of the global fish producers, representing a cumulative share of 36% in 2018 (FAO, 2020). As a top producer with 15% global share, China also remains as a top exporter of fish and fish products with 14% global market share.

There is *high agreement* in the literature that Asian fisheries and aquaculture, including the local communities depending on them for livelihoods, are highly vulnerable to the impacts of climate change. Asia has been impacted by sea level rise (Panpeng and Ahmad, 2017), decrease in precipitation in some parts (Salik et al., 2015) and increase in temperature (Vivekanandan et al., 2016) which have drastic effects on fisheries and aquaculture (FAO, 2018c). Its coastal fishing communities is exposed to disasters, which are predicted to increase (Esham et al., 2018). Fisheries in most of South Asia and Southeast Asian countries involve small scale fishers who are more vulnerable to climate change impacts compared to commercial fishers (Sönke Kreft et al., 2016; Blasiak et al., 2017) though there is a general decreasing trend in number of small units (Fernandez-Llamazares et al., 2015; ILO, 2015). A regional study of South Asia forecast large decreases in potential catch of two key commercial fish species (hilsa shad and Bombay duck) in the Bay of Bengal (Fernandes et al., 2016) which forms a major fishery and food for coastal communities. About 69% of the commercially important species of the Indian marine fisheries were found to be impacted by climate change and other anthropogenic factors (Dineshbabu et al., 2020). Likewise, water salinisation brought about sea level rise is expected to impact on the availability of freshwater fish in Southwest coastal Bangladesh with adverse implications to poor communities (Dasgupta et al., 2017a). Analysis of fishery has indicated that there will be continued decrease in catch impacting the seafood sector in Philippines, Thailand, Malaysia and Indonesia (Nong, 2019). Climate change was predicted to decrease total productive fisheries potential in

South and Southeast Asia, driven by a temperature increase of approximately 2 °C by 2050 (Barange et al., 2014).

Like fisheries, Asian aquaculture is highly vulnerable to climate change. Shrimp farmers and fry catchers of Bangladesh are frequently affected by extreme climatic disruptions like cyclones and storm surges that severely damage the entire coastal aquaculture (Islam et al., 2016a; Kais and Islam, 2018). Majority of the shrimp farmers also observed that weather has changed abruptly during the last 5 years and that high temperature is most detrimental, lowers growth rate, increases susceptibility to diseases including deformation and affect production (Islam et al., 2016a). Low production in shrimp farming is also attributed to variation and intensity of rainfall perceived by majority of farmers as part of climate change impacts (Ahmed and Diana, 2015; Islam et al., 2016a; Henriksson et al., 2019). In Vietnam, small scale shrimp farmers are likewise vulnerable to climate change although those who practice extensive type of farming with low inputs are more vulnerable compared to those who practice more intensive type with more capital investment (Quach et al., 2015; Quach et al., 2017). Seaweed farming in Asia is very popular and the significance of seaweed aquaculture beds (SAB) in capturing carbon is recognised, but most of the farmed seaweeds are susceptible to climate change (Chung et al., 2017a; Duarte et al., 2017).

MHW are a new threat to fisheries and aquaculture (Froehlich et al., 2018; Frölicher and Laufkötter, 2018) including disease spread (Oliver et al., 2017), live feed culture (copepods) (Doan et al., 2018), and farming of finfishes like Cobia (Le et al., 2020). Predicting MHW is considered a pre-requisite for increasing the preparedness of farmers (Frölicher and Laufkötter, 2018). In Southeast Asian countries more than 30% of aquaculture areas are predicted to become unsuitable for production by 2050 - 2070 and aquaculture production is predicted to reduce 10% - 20% by 2050 - 2070 due to climate change (Froehlich et al., 2018).

10.4.5.2.2 Crop production

Since IPCC AR5, more studies have been done in different scales from local to global that focus on the differentiated projected impacts of climate change on the production and economics of various crops with rice, maize, and wheat among the major crops receiving more attention. New research findings affirm that climate change impacts on and will continue to significantly affect crop production in diverse ways in particular areas all over Asia (See Figure 10.6). Increasing number of sub-regional and regional studies using various modelling tools provide significant evidences on the overall projected impacts of climate change on crop production at the sub-regional and regional scales with clear indications of winners and losers among and within nations ((see for instance, (Mendelsohn, 2014; Cai et al., 2016; Chen et al., 2016b; Schleussner et al., 2016)).

Beyond the usual research interest on crop yields which has dominated current literature, recent studies such as those in Japan started to focus on the impacts of climate change on the quality of crops (see for instance, Sugiura et al. (2013) for apple, and Morita et al. (2016) and Masutomi et al. (2019) for rice). A large-scale evaluation by Ishigooka et al. (2017) shows that the increased risk in rice production brought about by temperature increase may be avoided by selecting an optimum transplanting date considering both yield and quality. More studies of this nature have to conducted for other crops in different locations to better understand and adapt to the negative impacts of the changing climate on the quality of crops (Ahmed and Stepp, 2016).

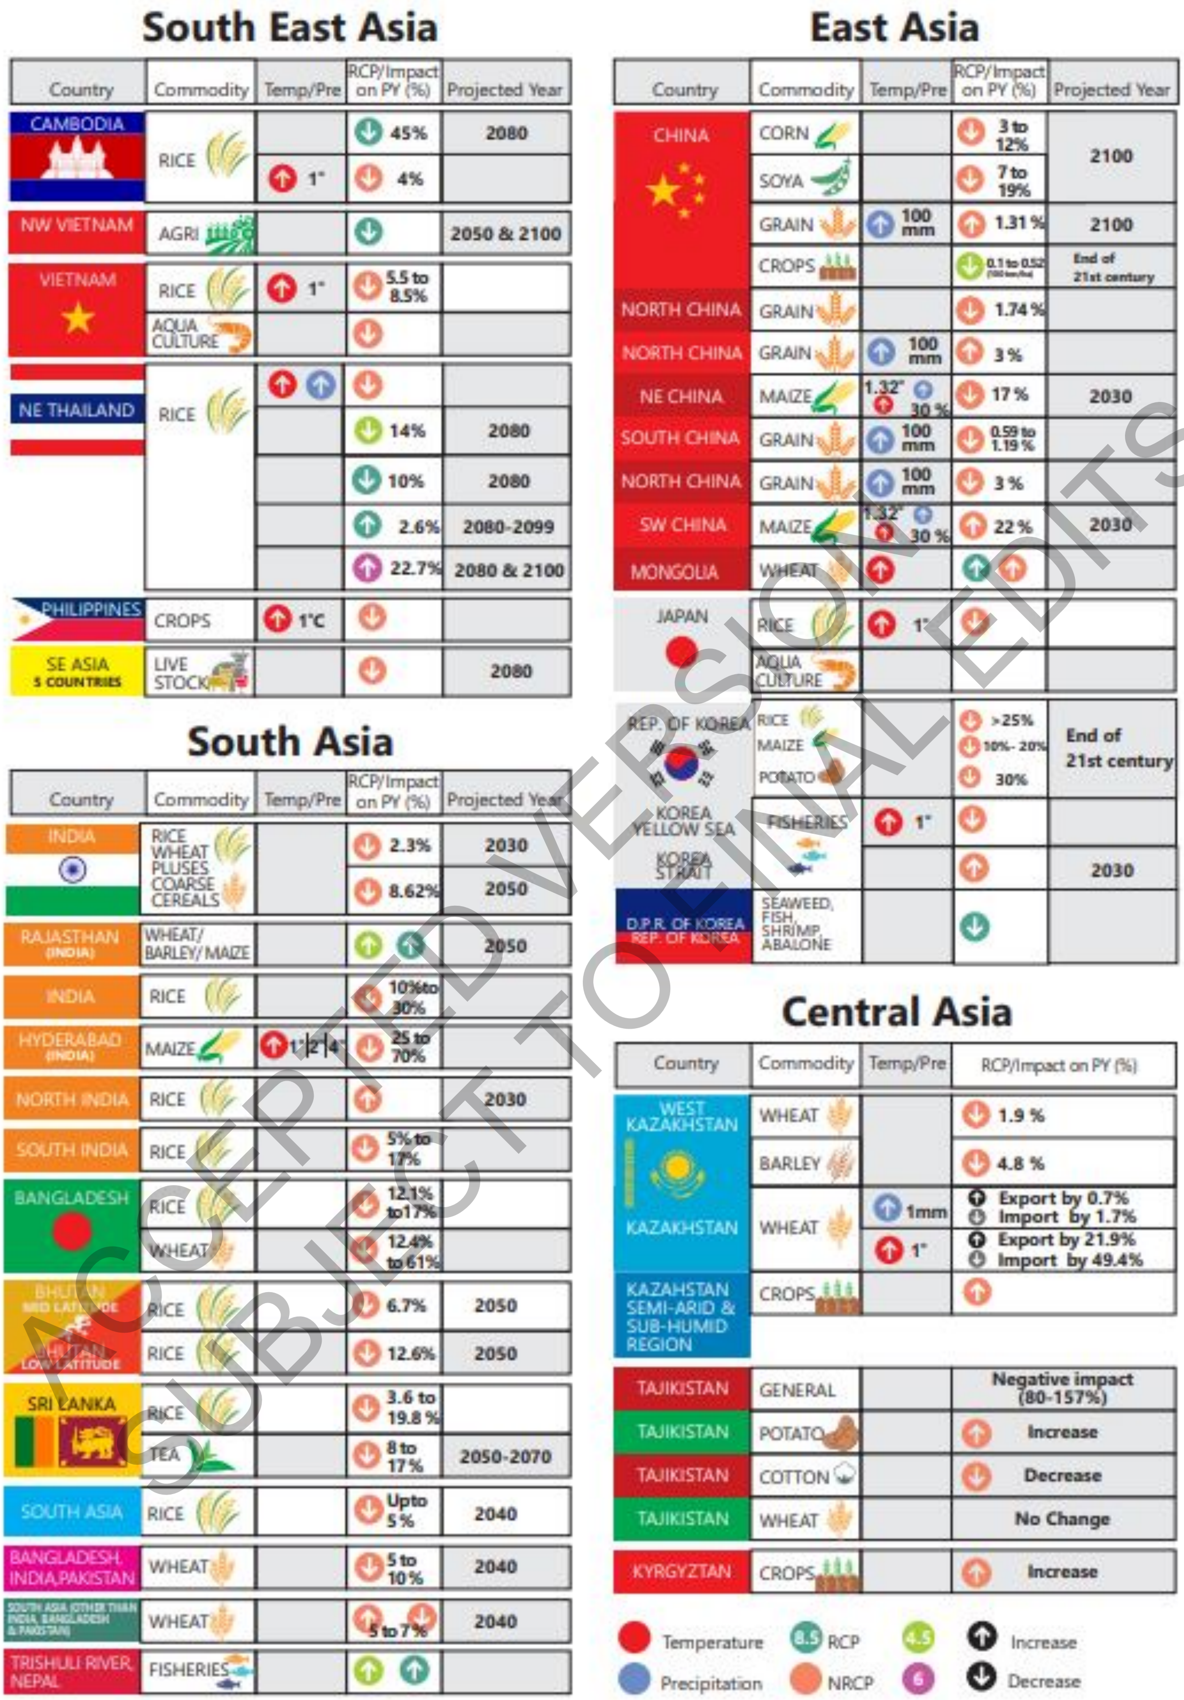

Figure 10.6: Projected impacts of climate change to agriculture and food systems in sub-regions of Asia based on post IPCC-AR5 studies. The figure illustrates the spatial and temporal diversity of projected future impacts on food production highlighting that there are winners and losers associated with the changing climate at different scales. (Abbreviations AGRI-Agriculture; E-East; N-North; NRCP-No RCP analysis; Pre-Precipitation; PY-Production Yield;

RCP-Representative Concentration Pathway; S-South; Temp-Temperature; W-West). (Please refer to Table SM10.2 for details and supporting references).

New studies have projected the *likely* negative impact of pests in Asian agriculture. The golden apple snail (*Pomacea canaliculate*), which is among the world's 100 most notorious invasive alien species, threatens the top Asian rice-producing countries including China, India, Indonesia, Bangladesh, Vietnam, Thailand, Myanmar, Philippines, and Japan with the predicted increase in climatically suitable habitats in 2080 (Lei et al., 2017). Similarly, a study by (Shabani et al., 2018) in Oman projected that pest of date palm trees, Dubas bug (*Ommatissus lybicus* Bergevin) could reduce the crop yield by 50% under future climate scenarios.

While there is general agreement that CO2 promotes growth and productivity of plants through enhanced photosynthesis, there remains uncertainty on the extent to which carbon fertilisation will influence agricultural production in Asia as it interacts with increasing temperatures, changing water availability, and the different adaptation measures employed (Ju et al., 2013; Jat et al., 2016; ADB, 2017b). As global warming compounds beyond 1.5 °C, however, the likelihood of adverse impacts to agricultural and food security in many parts of developing Asia increases (Mendelsohn, 2014; IPCC, 2018b). There is a growing trend towards more integrated studies and modelling that combines biophysical and socioeconomic variables (including management practices) in the context of changing climate to reduce uncertainty associated with future impacts of climate change to the agricultural sector ((see for instance (Mason-D'Croz et al., 2016; Smeets Kristkova et al., 2016; Gaydon et al., 2017)).

10.4.5.2.3 Livestock production

There is hardly any mention about the impacts of climate change on livestock production in the Asia chapter of AR5 due to limited studies on this area. This scarcity of information persists to the current assessment with very scanty information on the projected impacts and adaptation aspects of livestock production (Escarcha et al., 2018a). The use of scenarios/models to determine alternative futures with participatory engagement process has been recommended for informed policy and decision making with potential application in the livestock sector (Mason-D'Croz et al., 2016). Of the limited assessment available, a study on the smallholders' risk perceptions of climate change impacts on water buffalo production systems in Nueva Ecija, Philippines identified feed availability and animal health as the production aspects most severely affected by multiple weather extremes (Escarcha et al., 2018b). In the Mongolian Altai Mountains, early snowmelt and an extended growing season have resulted in reduced herder mobility and prolonged pasture use, which has in turn initiated grassland degradation (Lkhagvadorj et al., 2013a). Furthermore, reduced herder mobility has increased the pressure on forests resulting in increased logging for fuel and construction wood and reduced regeneration due to browsing damage by increasing goat populations (Khishigjargal et al., 2013; Dulamsuren et al., 2014).

In terms of direct impacts, climate change-induced heat stress and reduced water availability are *likely* to generally have negative effects on livestock (ADB, 2017b). In Hindu Kush-Himalaya (HKH) Region climate change has induced severe impacts on livestock through degradation of rangelands, pastures, and forests (Hussain et al., 2019). However, indirect effects maybe positive such as in Uzbekistan and South Asia where alfalfa and grassland productivity is expected to improve under warming conditions which have beneficial effects to livestock production (Sutton et al., 2013; Weindl et al., 2015).

At the global level, analysis involving 148 countries in terms of the potential vulnerability of their livestock sector to climate and population change shows that some Asian nations, particularly Mongolia, are *likely* to be the most vulnerable while South Asia is the most vulnerable region (Godber and Wall, 2014).

10.4.5.2.4 Farming systems and crop areas

There is new evidence since AR5 that farming systems and crop areas will change in many parts of Asia in response to climate change. In South Asia, a study in Nepal showed that farmers are inclined to change in cropland-use to reduce climate change risk (Chalise and Naranpanawa, 2016). In India, climate change is also predicted to lead to boundary changes in areas suitable for growing certain crops (Srinivasa Rao et al., 2016). A study in Bangladesh reveals a shift in crop choices among farmers implying changes in future rice cropping pattern. Specifically, temperature increase will compel farmers to choose irrigation based Boro, Aus and other crops in favor of rainfed Aman rice crop (Moniruzzaman, 2015).

In the coastal area of Odisha in India, adverse impact on the agriculture sector is anticipated considering the increasing temperature trends over the last 30 years for all the seasons (Mishra and Sahu, 2014). In a national study that groups Bangladesh into 16 sub-regions with similar farming areas, simulations of a 62 cm rise in mean sea level project damages to production because of area loss in excess of 31% in Sub-Region -15 and nearly 40% in Sub-Region -16 (Ruane et al., 2013). Also in Bangladesh, a study on predicting design water requirement of winter paddy rice under climate change condition shows that agricultural water resource management will help minimise drought risk and implement future agricultural water resources policies (Islam et al., 2018) that may have important implications to crop areas and production.

In East Asia, observed changes in agricultural flooding in different parts of China could influence farming systems and crop areas (Zhang et al., 2016b), as extreme events intensify in the context of changing climate. Agricultural management practice in China may also change to optimise soil organic carbon sequestration (Zhang et al., 2016a). A study on projected irrigation requirements under climate change using soil moisture model for 29 upland crops in Republic of Korea shows that water scarcity is a major limiting factor for sustainable agricultural production (Hong et al., 2016). In terms of drought, despite increasing future precipitation in most the scenario, crop-specific agricultural drought will be expected to risky significantly by rainfall variability (Lim et al., 2019a). On the other hand, a projected rise in water availability in the Korean Peninsula using multiple regional climate models and evapotranspiration methods indicates it will *likely* increase agricultural productivity for both rice and corn, but would decrease significantly in rainfed conditions (Lim et al., 2017b). Thus, irrigation and soil water management will be a major factor in determining future farming systems and crop areas in the country.

Global study on climate change-induced hot-spots of heat stress on agricultural crops shows that large suitable cropping areas in Central and Eastern Asia and the Northern part of the Indian subcontinent are under heat stress risk assuming the A1B emission scenario (Teixeira et al., 2013) and hence may reduce cropping areas in these regions. In Japan, the projected decline in rice yield in some areas, suggests that the current rice producing regions would be divided into suitable and unsuitable areas as temperatures increases (Ishigooka et al., 2017) with important implication on the possible shift in cropping area. Similarly, it has been shown that there will be change in the geographical distribution of the occurrence of poor skin color of table grape berries (Sugiura et al., 2019) and suitable areas for cultivation of subtropical citrus (Sugiura et al., 2014) in Japan by the middle of the 21st century.

There is emerging evidence from modelling and field experimentation that designing future farming systems and crop area that will promote sustainable development in Asia in the context of climate change would have to incorporate not only productivity and price considerations but also moderating temperature increase, enhancing water conservation, and optimising GHG mitigation potential (Sapkota et al., 2015; Zhang et al., 2016a; Ko et al., 2017; Lim et al., 2017b). Effects of agricultural landscape change on ecosystems services also need to be understood and taken into account in designing farming systems and allocating farm areas (Lee et al., 2015b; Zanzanaini et al., 2017).

10.4.5.3 Food Security

FAO (2001) defines food security as "a situation that exists when all people, at all times, have physical, social and economic access to sufficient, safe and nutritious food that meets their dietary needs and food preferences for an active and healthy life". There is significant evidence that climate change significantly undermines both agricultural production and food security in Asia (ADB, 2017b). Increasing evidence from sub-regions and individual countries suggests that climate-related hazards such as increasing temperature, changing rainfall, sea level rise, drought, flooding, and the more frequent and intense occurrence of ENSO events, all impacts on agricultural production with significant effects on food security. All these hazards interact with non-climatic factors like competing demand for scarce water resources, rural-urban migration, food prices and increasing food demand in the long term, and poor governance, among others, that may worsen food insecurity in the region (Montesclaros and Teng, 2021).

In West Asia, particularly in Saudi Arabia and Yemen, increasing water scarcity brought about by temperature rise is anticipated to have severe impact on agriculture and food production that undermines food security (Al-Zahrani et al., 2019; Baig et al., 2019). Saudi Arabia, for instance, was forced to phase out its wheat production starting in 2016 and fully rely on import to conserve its drying fossil water resources (Al-Zahrani et al., 2019) which is also linked to water governance issue.

In Central Asia, a study using bioeconomic farm model shows very large differences in climate change impacts across farming systems at the sub-national level. Large-scale commercial farms in the northern regions of Kazakhstan will have positive income gains while small-scale farms in arid zones of Tajikistan will experience negative impact with *likely* effects to farm income security (Bobojonov and Aw-Hassan, 2014). Impacts on farmers' income in Western Uzbekistan will also significantly vary and could fall by as much as 25% depending on the extent of temperature increase and water use efficiency (Bobojonov et al., 2016).

In a regional study among South Asian countries using an integrated assessment modelling framework, changes in rice and wheat productions brought about by climate change are anticipated to engender wild price volatilities in the markets (Cai et al., 2016). Price spikes are projected for the period 2015 to 2040 in all South Asian regions with India, Pakistan and Sri Lanka predicted to witness increasingly much higher rice and wheat prices than under the baseline scenario creating major concerns over food affordability and food security. This will *likely* severely affect the overall economic growth of these countries since they are mainly agriculture driven economy.

A study on mapping global patterns of drought risk projected an increase of drought frequency and intensity in the populated areas of South to Central Asia extensively used for crop and livestock production with serious repercussion to food security and potential civil conflict in the medium- to long-term (Carrão et al., 2016). In Southeast Asia, a Philippine study on the relationship of seasonal rainfall, agricultural production, and civil conflict suggests that the projected change towards wetter rainy seasons and drier dry seasons in many parts of the country will lead to more civil conflict (Crost et al., 2018) with negative implications to food and human security. Similarly, floods and higher food prices are also associated with higher risks of social unrest in Asia that may undermine food security (Hendrix and Haggard, 2015; Ide et al., 2021).

Food insecurity will be localised across Asia where one part of the country or sub-region will be more food secured while the others, more insecure. This will require in-country or sub-regional trade and development cooperation to minimise the adverse impacts of food insecurity associated with the changing climate (Li et al., 2014a; Abid et al., 2016).

10.4.5.4 Key Drivers to vulnerability

There is *high confidence* that agriculture will continue to be among the most vulnerable sectors in Asia in the light of the changing climate (Mendelsohn, 2014; ADB, 2017b). Among the more vulnerable areas include mountain agriculture where fluctuation in crop production (Poudel and Shaw, 2016; Hussain et al., 2019) and food insufficiency is widespread than in lowland areas (Poudel and Shaw, 2015); (Kohler and Maselli, 2009). Also vulnerable are flood-prone areas like the Vietnam Mekong River Delta where 39% of the total rice area is exposed to sustained flood risks (Wassmann et al., 2019a). Increasing temperatures and changing precipitation levels will persist to be important vulnerability drivers that will shape agricultural productivity particularly in South Asia, Southeast Asia, and Central Asia as well as in selected areas of the region. With the increasing likelihood of extreme weather events like strong typhoons in the Philippines, the agricultural sector in the typhoon-prone areas of Southeast and East Asia as well as the Indus Delta, will be more vulnerable to crop destruction (Mallari and Ezra, 2016). Projections on increasing sea level rise and flooding such as those in Bangladesh and the Mekong Delta in Vietnam will submerge and decrease crop production areas and will severely affect agriculture and fishery sectors but will also trigger outmigration from these areas (ADB, 2017b).

Vulnerability of aquaculture-related livelihoods to climate change was assessed at the global scale using the MAGICC/SCENGEN climate modelling tools and Vietnam, Thailand were identified as most vulnerable in brackish water aquaculture production (Handisyde et al., 2017). Asian countries like China, Vietnam and the Philippines are also ranked highly vulnerable in marine production. Moreover, a recent vulnerability assessment of Korean aquaculture based on predicted changes in seawater temperature and salinity according to representative concentration pathways (RCP) scenario (RCP8.5) indicated that vulnerability was highest for seaweed, such as laver and sea mustard, while fish, shrimp, and abalone are relatively less vulnerable as they are less sensitive to high water temperature and their farming environments are controllable to a large extent (Kim et al., 2019a). In Indonesia, farming of white leg shrimp *Litopenaeus vannamei* has been found to be vulnerable to increased rainfall and temperature decrease (Puspa et al., 2018).

Climate change-induced vulnerability however is complicated by non-climatic drivers. In Thailand, for instance, a 38% reduction (from 21,486 to 13,328 million baht) in the export values of rice and products in the last quarter of 2011 has been attributed not only to impact of tropical cyclone Nock-Ten on Thai rice export but also with the economic slowdown in Thailand during 2011-2012 (Nara et al., 2014).

Considering the high vulnerability of Asia to climate change as a whole, there is a need to look at the drivers of vulnerability in an integrated and comprehensive manner. The increasing interest on nexus studies that links climate change impacts to agriculture with the other sectors like water, energy, land use change, urbanisation, poverty, economic liberalisation, and others ((see for example, (Takama et al., 2016; Aich et al., 2017; Eslamian et al., 2017; Duan et al., 2019b)) could contribute to a systemwide vulnerability reduction and an important initial step towards a more climate resilient future.

10.4.5.5 Adaptation Options

Since AR5, there is a surge in the volume of literature that documents and assesses the different adaptation practices already employed in Asian agriculture as well as those that provide future adaptation options. There is *robust evidence* that a variety of adaptation practices already employed in agriculture and fisheries are valuable in reducing negative effects of current climate anomalies but may not be sufficient to fully offset the adverse impacts of future climate scenarios. Recent literature, therefore focuses on how to build on current adaptation initiatives and processes to improve current and future outcomes (Iizumi, 2019).

Asian farmers and fisherfolks already employ a variety of adaptation practices to minimise the adverse impacts of climate change. A recent systematic and comprehensive review of farmers' adaptation practices in Asia, Shaffril et al. (2018) categorised these practices into different forms such as crop management, irrigation and water management, farm management, financial management, physical infrastructure management, and social activities. "Climate-smart agriculture" - an integrated approach for developing agricultural strategies that address the intertwined challenges of food security and climate change – is increasingly being promoted in many parts of the region, especially in Southeast and South Asia with potentially promising outcomes (Chandra et al., 2017; Khatri-Chhetri et al., 2017; Shirsath et al., 2017; Westermann et al., 2018; Wassmann et al., 2019b). Site specific adaptations such as those in Pakistan include the farmers' utilisation of several adaptation techniques which include changing crop type and variety and improving seed quality; fertiliser application and use of pesticides and plant shade trees; and water storage and farm diversification (Fahad and Wang, 2018), as well as the implementation of a comprehensive climate information services to farming communities (World Meteorological Organization, 2017).

Adaptation measures are also beneficial to small scale fishers and fish farmers (Miller et al., 2018) and through fisheries management plans (FMP) and early warning systems, the Asian region is reducing climate impact (FAO, 2018c). The most common FMPs adopted in different Asian countries are limits to fishing gear, licensing schemes and seasonal closures (ILO, 2015) protection of nursery grounds, providing alternative livelihoods (Azad, 2017), limiting fish aggregating devices (FADs) and introduction of monitoring and control tool (Department of Fisheries (Thailand), 2015). Fishers' strong sense of belonging to their place of residence and the sense of responsibility to protect the vulnerable fish stock has been advantageously used for developing cooperatives and starting community-based fisheries management (FAO, 2012; ILO, 2015; Shaffril et al., 2017) and these have yielded positive results.

In aquaculture, most households in shrimp communities rely on process-oriented multiple coping mechanisms such as consumption smoothing, income smoothing, and migration that enhance the farmers' resilience to climate anomalies (Kais and Islam, 2018). Diversification and integration of varied resources and interventions in feed and husbandry are seen help the aqua farmers increase their profit and overcome impacts of climate change (Henriksson et al., 2019). Strategies like polyculture, integrated multitrophic aquaculture (IMTA) and recirculating aquaculture systems (RAS), have been suggested to increase aquaculture productivity, environmental sustainability, and climate change adaptability (Ahmed et al., 2019c; Tran et al., 2020). In Bangladesh, several adaptation measures like integrated (Akber et al., 2017) community-based adaptation strategies and integrated coastal zone management (Ahmed and Diana, 2015) have been recommended to increase climate resilience among shrimp farmers.

More recently, Nature-based Solutions (NbS) have gained attention globally to enhance climate adaptation. In the context of agriculture, NbS is seen as cost-effective interventions that can increase resilience in food production, while advancing climate mitigation and improving the environment (Iseman and Miralles-Wilhelm, 2021). Experiences in implementing NbS in agricultural landscapes have been documented both in agriculture and fisheries sectors that promotes production while providing co-benefits such as environmental protection and sustainability (Miralles-Wilhelm, 2021).

Despite the numerous adaptation measures already employed, there is sufficient evidence that farmers' current adaptation practices are inadequate to offset the worsening climate change impacts. A more comprehensive approach that integrates economic and social strategies with other measures is seen to reduce climate vulnerability. For instance, agriculture insurance is viewed as a promising adaptation approach to reduce risks and increase the financial resilience of farmers and herders in many Asian countries (Prabhakar et al., 2018; Matheswaran et al., 2019; Nguyen et al., 2019; Stringer et al., 2020). Similarly, participation of multiple stakeholders from all relevant sectors at different levels in adaptation planning and decision-making is seen as important factor in improving outcomes (Arunrat et al., 2017; Hochman et al., 2017; Chandra and McNamara, 2018). Moreover, while adaptation is local and context-specific, the following general adaptation-related strategies are distilled from current literature based on Asian experience to enhance current and future adaptations: 1) create enabling policies (Chen et al., 2018d) and enhance institutional capacity (Wang et al., 2014; Hirota and Kobayashi, 2019); 2) improve adaptation planning and decision-making (Xu and Grumbine, 2014; Asmiwyati et al., 2015; Dissanayake et al., 2017; Hochman et al., 2017; Qiu et al., 2018; Shuaib et al., 2018; Aryal et al., 2020b; Ruzol et al., 2021; Ruzol and Pulhin, 2021); 3) promote science-based adaptation measures (Alauddin and Sarker, 2014; Sapkota et al., 2015; Lim et al., 2017b); 4) adopt an integrated approach to improve adaptation (Teixeira et al., 2013; Yamane, 2014; Abid et al., 2016; Sakamoto et al., 2017; Sawamura et al., 2017; Trinh et al., 2018); 5) invest on critical infrastructure (Cai et al., 2016; Rezaei and Lashkari, 2018); and 6) address farmers' adaptation barriers (Alauddin and Sarker, 2014; Pulhin et al., 2016; Fahad and Wang, 2018; Gunathilaka et al., 2018; Almaden et al., 2019b) (See Figure 10.7 for details or examples of each strategy).

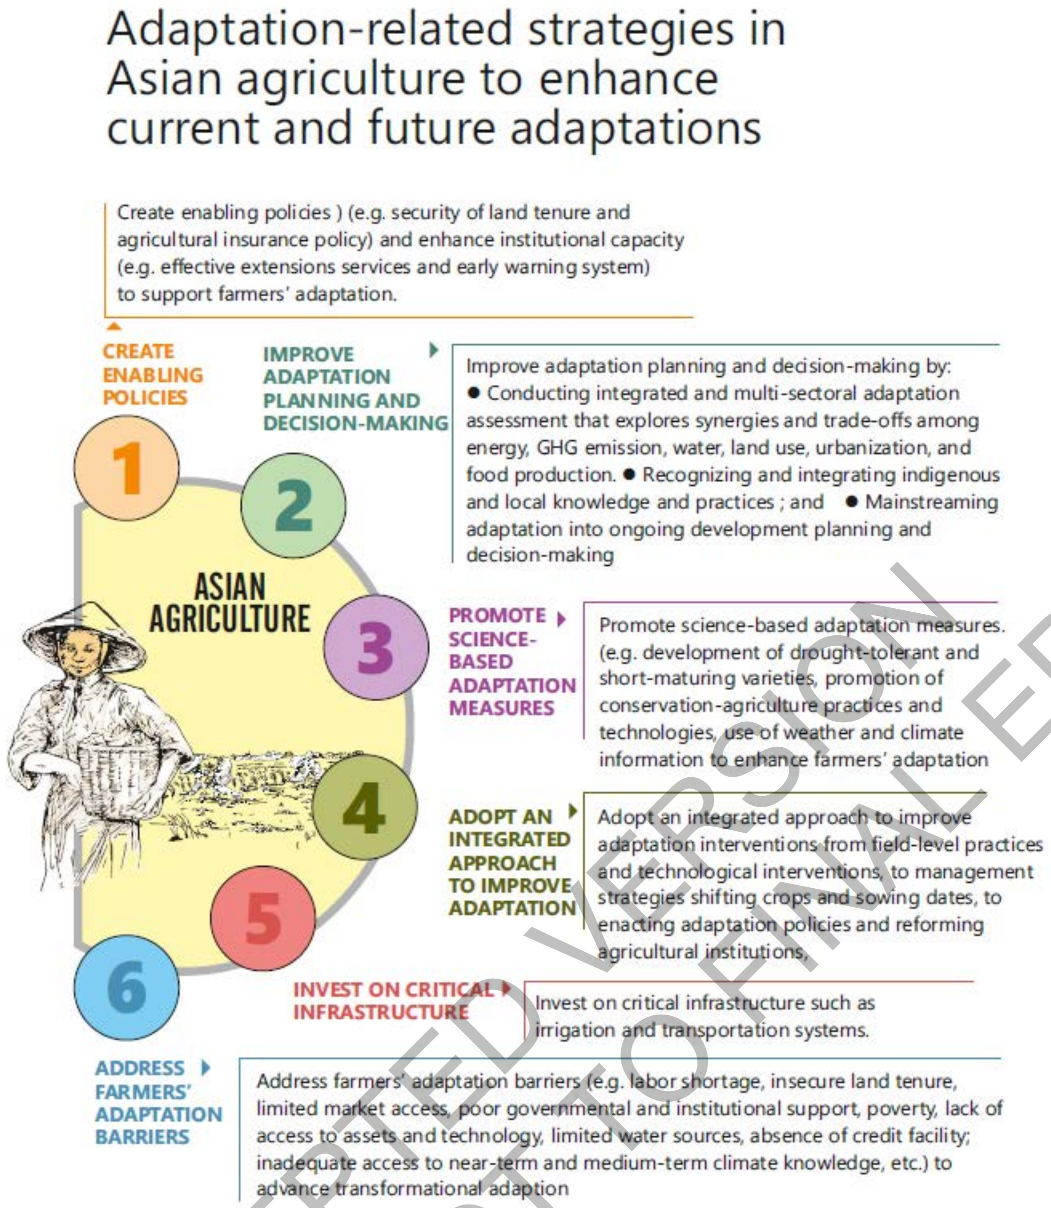

Figure 10.7: Adaptation related strategies in Asian agriculture to enhance current and future adaptations.

10.4.6 Cities, Settlements, and Key Infrastructures

Cities across Asia have large populations exposed to climatic risks but also present an opportunity for concerted climate action (Revi et al., 2014; Chu et al., 2017; Revi, 2017; Khosla and Bhardwaj, 2019) and report numerous examples of adaptation actions at various stages of planning and implementation (Dulal, 2019) (Singh et al., 2021b). However, challenges specific (though not exclusive) to Asian cities such as uneven economic development, rapid land use changes, increasing inequality, growing exposure to extreme events and environmental change such as land subsidence (with antecedent impacts on people and infrastructure), and large, socially differentiated vulnerable populations, remain key concerns as Asian cities simultaneously tackle challenges of sustainable development and equitable climate action.

10.4.6.1 Sub-regional diversity

By 2050, urban areas are expected to add 2.5 billion people, 90% of which will be in Asia and Africa (UNDESA, 2018). Critically, this urban population increase will be concentrated in India, China and Nigeria with India and China adding 416 million and 255 million urban dwellers respectively between 2018 and 2050 (UNDESA, 2018).

Asia is home to 54% of the world's urban population and by 2050, 64% of Asia's 3.3 billion people will be living in cities. Asia is also home to the world's largest urban agglomerations: Tokyo (37 million inhabitants), New Delhi (29 million), and Shanghai (26 million) are the top three with Cairo, Mumbai, Beijing and Dhaka home to nearly 20 million people each (UNDESA, 2018). By 2028, Delhi is projected to become the most populous city in the world. In certain parts of Asia (e.g. some cities in Japan and Republic of Korea), a steep decline in urban population is projected, mainly due to declining birth rates (Hori et al., 2020). Within Asia, rates of urbanisation differ sub-regionally. Eastern Asia has seen the most rapid urban growth with the percentage of urban population having more than tripled from 18 to 60 percent between 1950 and 2015, while rates of urbanisation have reduced in West Asia and remained steady in Central Asia (UNDESA, 2018).

Asian cities are seeing growing income inequality, with rural poverty being replaced by urban poverty (ADB, 2013). Regional studies show high and growing inequality within Indian and Chinese urban areas and reducing rural-urban income gaps in Thailand and Viet Nam (Baker and Gadgil, 2017; Imai and Malaeb, 2018). Critically, East Asia and the Pacific continues to house the world's largest population of slum dwellers at 250 million, with most numbers in China, Indonesia, and the Philippines and highest rates of urban poverty in Papua New Guinea, Vanuatu, Indonesia, and the Lao People's Democratic Republic (PDR) (McIlreavy, 2015; Baker and Gadgil, 2017). A lot of urbanisation, especially in South Asia, is also 'hidden' due to poor competing definitions of what is urban and limited data (Ellis and Roberts, 2016).

10.4.6.2 Key drivers of vulnerabilities

In Asian cities, exposure to climatic hazards such as changes in precipitation and in the Asian monsoon, sea level rise, cyclones, flooding, dust storms, heat waves, and permafrost thawing (Byers et al., 2018; Hoegh-Guldberg et al., 2018; Rogelj et al., 2018; Shiklomanov, 2019) and non-climatic vulnerabilities such as non-climatic hazards (e.g. seismic hazards), inadequate infrastructure and services, unplanned urbanisation, socio-economic inequalities, and existing adaptation deficits (Johnson et al., 2013; Araos et al., 2016; de Leon and Pittock, 2017; Meerow, 2017; Dulal, 2019) interact to shape overall urban risk (Shaw et al., 2016a; Rumbach and Shirgaokar, 2017; Dodman et al., 2019). Caught at the intersection of high exposure, socio-economic vulnerability, and low adaptive capacities, informal settlements in urban and peri-urban areas are particularly at risk (Meerow, 2017; Rumbach and Shirgaokar, 2017; Byers et al., 2018) (*robust evidence, high agreement*).

10.4.6.3 Observed and projected impacts

10.4.6.3.1 Multi-hazard risk

Of the multi-hazard global Average Annual Loss (AAL[3]) of US$293 billion, US$170 billion (58%) is in the Asia Pacific region (UNISDR, 2017). Of the top ten highest AALs associated with multi-hazards, six are in Asia (Japan, China, Korea, India, Philippines and Taiwan, Province of China) (UNISDR, 2017). As per Gu et al. (2015), 56% cities with population greater than 300,000 in 2014, are exposed to at least one of the six physical hazards (cyclones, floods, droughts, earthquakes, landslides, and volcanic eruptions). Cities in areas highly exposed and vulnerable to multiple hazards were also the ones that grew rapidly in population between 1950 and 2014, implying greater infrastructural investments in climate-sensitive areas. Among 27 cities highly exposed to multiple disasters, 13 cities had a population of 1 million or more in 2014. Among these were three megacities, Tokyo (Japan), Osaka (Japan) and Manila (Philippines), with more than 10 million inhabitants exposed to three or more hazards. Seven other cities with one million inhabitants or more in Asia were at high risk of three or more types of disaster. Manila is highly vulnerable to economic losses and disaster related mortality from all six types of disasters (Gu et al., 2015). Moscow (Russia) is the only megacity not exposed to the risk of any of the six types of physical hazards analysed (cyclones, floods, droughts, earthquakes, landslides, and volcano eruptions) (Gu et al., 2015). Of the eight megacities most vulnerable to disaster-related mortality, seven are in Asia, mainly Tokyo, Osaka, Karachi, Kolkata, Manila, Tianjin, and Jakarta, totalling 143 million people, and three of the four large cities with a population between

[3] Average Annual Loss (AAL) is the average amount that a country could expect to lose each year over the long-term due to hazard incidence. It corresponds to the expected average loss per year considering all the events that could occur over a long time-frame, including very intensive events. It is a probabilistic indication of the direct economic losses expected due to total or partial damage of physical assets existing in the affected area. (UNISDR, 2017).

5 million to 10 million: are in Asia: Chennai (India, 9.6 million), Nagoya (Japan, 9.4 million), and Tehran (Iran, 8.4 million) (Gu et al., 2015).

10.4.6.3.2 Extreme temperatures and heat waves

Urbanisation and climate change interact to drive urban heat island (UHI) effect across Asian cities (Chapman et al., 2017) (Hauck et al., 2016) [also see Fig 6.4 in Ch 6]. Three regions expected to see higher maximum wet bulb temperature than global averages are southwest Asia around the Persian Gulf and Red Sea, South Asia in the Indus and Ganges river valleys, and eastern China (Im et al., 2017) (Perkins-Kirkpatrick et al., 2020).

Impacts of heat waves in cities at 1.5°C and 2°C are substantially larger than under the present climate (Hoegh-Guldberg et al., 2018). In South Asia particularly, more intense heat waves of longer durations and occurring at a higher frequency are projected with *medium confidence* over India (Murari et al., 2015) and Pakistan (Nasim et al., 2018; Ali et al., 2020) (Ali et al., 2018) (IPCC AR6, WGI, Table 11.5)(IPCC, 2021a). At the city-level, these projections could translate into significant impacts: at 1.5°C, on average, Kolkata will experience, heat equivalent to the 2015 record heat waves every year; Karachi about once every 3.6 years and under 2°C warming, both regions could expect such heat annually (Matthews et al., 2017). In Pakistan, Hyderabad is *likely* to be the hottest city by 2100 with the highest average temperature reaching upto 29.9°C (RCP4.5) to 32°C (RCP8.5) followed by Jacobabad, Bahawalnagar, and Bahawalpur cities (Ali et al., 2020). The frequency of heat wave days (HWF) will increase by 22.8, 22.3, and 26.5 days/year in northern, eastern, and western Japan, respectively with megacities such as Tokyo, Osaka, and Nagoya seeing large increases in HWF and related deaths (Nakano et al., 2013).

In China's urban agglomerations, an increase in the global warming from 1.5 to 2°C is *likely* to exacerbate the intensity of extreme maximum temperature 4.1 times (Yu et al., 2018d). From 1995–2014 China's urban agglomerations (Beijing-Tianjin-Hebei, Yangtze River Delta, Middle Yangtze River, Chongqing-Chengdu, and Pearl River Delta (PRD)) experienced no more than three heat danger days/year, which is projected to increase to 3–13 days by 2041–2060 and 8-67 days by 2081–2100 under high-emission shared socioeconomic pathways SSP3-7.0 and SSP5-8.5, resulting in approximately 260 million people (19% of total Chinese population) and 310 million people (39% of the total China population) respectively facing more than three heat danger days annually (Zhang et al., 2021). This projected risk exposure is reduced under low-emission pathways (SSP1-2.6 and SSP2-4.5), where annual heat danger days will remain similar to current levels or increase slightly (Zhang et al., 2021).

Critically, these projections of higher temperatures will have significant impact on heat-related morbidity and mortality, labour productivity, mental health impacts and health and well-being outcomes across all sub-regions of Asia (*medium evidence, high confidence*) (Im et al., 2017) (Pal and Eltahir, 2016; Arifwidodo et al., 2019; Arshad et al., 2020). In West Asia and North China Plain especially, extreme wet-bulb temperatures are expected to approach and possibly exceed the physiologic threshold for human adaptability (35°C) (Pal and Eltahir, 2016; Kang and Eltahir, 2018). By end century, under higher projections (RCP 8.5) daily maximum wet-bulb temperature is expected to exceed survivability threshold across most of South Asia (Im et al., 2017). City-specific studies articulate what these regional projections will mean for urban populations. For example, at 1.5 °C warming, without adaptation, annual heat-related mortality in 27 major cities across China is projected to increase from 32.1 per million inhabitants annually in 1986–2005 to 48.8–67.1 per million. This number increases to 59.2–81.3 per million for 2°C warming (Wang et al., 2019a). In Korea, deaths from heat disorders are expected to increase approximately fivefold under the RCP4.5 and 7.2-fold under RCP 8.5 by 2060 compared to the current baseline value of ~23 people/summer (Kim et al., 2016a). Importantly, heat exposure is differentiated within cities: it disproportionally affects the poorest populations (Lohrey et al., 2021) and those with lower access to green spaces (Arifwidodo and Chandrasiri, 2020).

10.4.6.3.3 Precipitation extremes: excess rainfall and drought and water scarcity

Warming from 1.5°C to 2°C will increase extreme precipitation events across Asia especially over East and South Asia (*medium evidence, high agreement*) (Zhang et al. 2018); (Zhang et al., 2020b) (Supari et al., 2020). In East and Central Asia, under 1.5°C warming, extreme 1-day and 5-day precipitation will increase by 28% and 15%, relative to 1971–2000 (Zhang et al., 2020b). In China's urban agglomerations, an increase in the global warming from 1.5 to 2°C is *likely* to increase the intensity of total precipitation of very wet days

1.8 times and double maximum 5-day precipitation (Yu et al., 2018d). Extreme rainfall has direct and increasing consequences on urban flooding risk (Dasgupta et al., 2013b), which is further exacerbated by urbanisation trends that reduce permeability, divert water flow, and disrupt watersheds (Chen et al., 2015b; Duan et al., 2016).

Urban extent in drylands in expected to increase from 2000-2030 with large expansions in West Asia, Central Asia, South Asia, and China with antecedent impacts on exposure to drought and water scarcity (Güneralp et al., 2015). Urban dryland extent in West Asia will increase from 19,400km^2 to 67,400km^2 (Güneralp et al., 2015). In the Haihe River Basin in China, the proportion of people exposed to droughts at 1.5ºC (without accounting for population growth) is projected to reduce by 30.4%, but increase by 74.8% at 2°C relative to people exposed in 1986–2005 (339.65 million) (Sun et al., 2017). 411 million people living in 330 cities above 300,000 population are exposed to drought risk, which include three Asian megacities Delhi (India), Karachi (Abbas et al.), and Kolkata (India). Drought-related economic losses are also high in Dhaka (Pervin et al., 2020), Istanbul (Turkey), Manila (Philippines), and Shenzhen (China), while Manila is also highly vulnerable to drought-related mortality (Gu et al., 2015).

Increasing urban drought risk will also have cascading impacts on regions from where water is imported, exacerbating drought exposure beyond urban settlements and limiting water availability in certain regions (Chuah et al., 2018; Garrick et al., 2019; Zhang et al., 2020c; Zhao et al., 2020). There is *medium evidence (high agreement)* that urban water insecurity is experienced differentially based on income, risk exposure, and assets, and that urban drought and water scarcity is causing material and on-material losses and damage (Singh et al., 2021a). Importantly, in several Asian cities, flood and drought risk is expected to occur concurrently, especially in South Asia which is projected to see the largest increase in urban land exposed to both floods and droughts (25% to 32% increase in flood and drought risk between 2000-2030).

10.4.6.3.4 Sea-level rise and coastal flooding

Global assessments identify Asia as the most exposed to SLR [see CCP 2.2.1], in terms of number of people living in low-elevation coastal zones and the number of people exposed to flooding from 1-in-100 year storm surge events (Jevrejeva et al., 2016; Abadie et al., 2020) (Neumann et al., 2015; Kulp and Strauss, 2019) (Haasnoot, 2021). Twelve of the top 20 countries exposed to SLR and associated flood events are in Asia and of these, China, India, Bangladesh, Indonesia and Viet Nam are estimated to have the highest total coastal population exposure (Neumann et al., 2015) (Edmonds et al., 2020). Critically, regardless of emissions scenario, 70% of the global population exposed to SLR and land subsidence are in eight Asian countries: China, Bangladesh, India, Vietnam, Indonesia, Thailand, the Philippines, and Japan (Kulp and Strauss, 2019). This is particularly concerning since in highly populated low-lying coastal cities across Asia, it is estimated that land subsidence could be as influential as climate-induced SLR over the twenty-first century (Cao et al., 2021; Nicholls et al., 2021). In East Asia & the Pacific (expected to see 0.2-0.5m SLR), without adaptation, 1 million people (range of 0.3-2.2 million) are projected to be affected by submergence under RCP8.5 by 2095. Limiting warming reduces this risk and under RCP 4.5, these numbers of people at risk are reached by 2140. However, continuing on RCP8.5 increases risk exposure to 7 million (estimated range of 2-24 million people) (Haasnoot, 2021). Notably, assuming present-day population and adaptation (in the form of existing protection standards), East and South Asia already have a large number of people at risk of a 100-year flooding event (63 million) because of relatively lower flood protection (except in China and Malaysia).

These global scenarios will have significant impacts on national and sub-national populations. For example, in Bangladesh, under 0.44m and 2m mean SLR, direct inundation is estimated to drive migration of 0.73- 2.1 million people by 2100 (Davis et al., 2018). Such migration will have direct development implications: for example, destination locations could see additional demands on jobs (594 000), housing (197000), and food (783×109 calories) by mid-century as a result of those displaced by SLR (Davis et al., 2018).

Among the 20 largest coastal cities with highest flood losses by 2050, 13 are in Asia[4], with a regional concentration in South, South East and East Asia (Hallegatte et al., 2013). Further, 9 of these cities (Guangzhou, Kolkata, Tianjin, Ho Chi Minh, Jakarta, Zhanjiang, Bangkok, Xiamen, Nagoya) also have an

[4] Guangzhou, Mumbai, Kolkata, Shenzhen, Tianjin, Ho Chi Minh, Jakarta, Chennai, Surat, Zhanjiang, Bangkok, Xiamen and Nagoya

additional risk of subsidence due to sea-level rise and flooding (Hallegatte et al., 2013). Guangzhou, China is estimated to be the most economically vulnerable city in the world to SLR by 2050, with estimated losses of $254 million per year under 0.2m SLR (Jevrejeva et al., 2016). With a 2°C warming, Guangzhou is expected to see SLR of 0.34m; under 5°C warming, this number rises to 1.93m. A more recent estimate calculates expected damage in Guangzhou due to SLR under RCP8.5 to reach US$331 billion by 2050 and US$420 billion under the high-end scenario with figures doubling by 2070. By 2100, expected damage could reach US$1.4 trillion under RCP 8.5 and US$1.8 trillion the high-end scenario. Similarly, in Mumbai (India) SLR damages amount to US$49-50 billion by 2050 and could increase by a factor of 2.9 by 2070 (Abadie et al., 2020). In coastal cities such as Bangkok and Ho Chi Minh City, projected land subsidence rates, mainly due to excessive groundwater extraction, are comparable to, or exceed, expected rates of SLR, resulting in an additional 0.2 m sea level rise by 2025 (Jevrejeva et al., 2016). In Shanghai, current annual damage by coastal inundation is estimated at 0.03% of local GDP; under RCP4.5, this increases to 0.8% by 2100 (uncertainty range: 0.4%–1.4%), and further exacerbated by land subsidence and socioeconomic development (Du et al., 2020). It is important to note that these projections assume (1) no adaptation and (2) that damage repairs are undertaken and completed annually. Given these assumptions, while these estimates communicate the scale of projected impacts, they are indicators of possible damages in the absence of adaptation and not actual projections.

SLR affects economic growth, its drivers, and welfare outcomes (Hallegatte, 2012; Pycroft et al., 2016; Lee and Asuncion, 2020) through (1) permanent loss of land and natural capital, (2) loss of infrastructure and physical capital, (3) loss of social capital and migration, (4) temporary floods, food insecurity and loss of livelihoods, and (5) added expenditure for coastal protection. Without adaptation, direct damage to GDP by 2080 due to SLR would be highest in Asia (*robust evidence, medium agreement*), with China losing between $64.2 billion (at A1B of 2.4∘C by the 2050s and 3.8∘C by the 2090s/ 0.47 m), $95.8 billion (at RAHM scenario of 1.4 m SLR by 2100/1.12 m), and $118.4 billion (at High SLR of 2m by 2100/1.75 m) in direct damages, and an additional $5.7 billion, $4.5 billion, and $4.5 billion respectively due to migration (Pycroft et al., 2016). Closely after China, will be India, Korea, Japan, Indonesia, and Russia. Overall, Asia can experience direct losses of about $167.6 billion (at 0.47 m), $272.3 billion (at 1.12m), or $338.1 billion (at 1.75m) and an additional $8.5 billion, $24 billion or $ 15 billion at the respective SLR projections due to migration[5].

10.4.6.3.5 Tropical cyclones

Globally, there is *high confidence* that the proportion of intense tropical cyclones is expected to increase despite the total number of tropical cyclones expected to decrease or remain unchanged (Arias et al., 2021), especially in Southeast and East Asia (Knutson et al., 2015; Yamamoto et al., 2021). Historical trends from South Asia indicate that more lives are lost due to storm surge levels than the intensity of the cyclone (Niggol and Bakkensen, 2017). The number of people exposed to 1-in-100-year storm surge events, is highest in Asia. China, India, Bangladesh, Indonesia and Viet Nam have the highest numbers of coastal populations exposed (Neumann et al., 2015) with Guangzhou, Mumbai, Shenzen, Tianjin, Ho Chi Minh City, Kolkata, and Jakarta incurring losses of US$1520 million due to coastal flooding in 2005 alone (Dulal, 2019), although Jakarta is exposed to monsoonal storm surge. It is projected that by 2050, without adaptation, the annual losses incurred in these cities will increase to approximately US$32 billion (Dulal, 2019).

Globally, six of the top ten countries/places with the highest AAL associated with tropical cyclones are in Asia (Japan, Korea, Philippines, China, Taiwan, Province of China, and India) (Mori et al., 2021a). AAL associated with storm surge is primarily concentrated in Japan, China, Hong Kong SAR of China, and India. AAL associated with wind and storm surge relative to the existing capital stock in the country is highest in New Caledonia, Tonga, Vanuatu, Palau, Philippines, Fiji and Solomon Islands, indicating less resilience. For example, in Ise Bay, Japan, current storm surges are estimated to lead to property and business damage of approximately 100.04 billion JPY current adaptation (protective seawall) but this can more than double to 236.49 billion JPY under climate change-induced increases in storm surge intensity (Jiang et al., 2016).

[5] Cumulative migration in high SLR scenarios is always higher, but since much of the migration has already occurred in earlier decades, the additional migration is lower in the high SLR scenarios than the A1B scenario.

10.4.6.3.6 Riverine floods

Over on-third Asian cities and about 932 million urban dwellers live in areas with high risk of flooding (Gu et al., 2015). Of 437 cities at low risk of flood exposure but highly vulnerable to flood-related economic losses, approximately half are in Asia (Gu et al., 2015).

Globally, China and India have the highest AALs associated with riverine floods, with a magnitude of USD 13 billion and USD 6 billion respectively. Other countries from Asia among the top ten of absolute AALs are Japan, Bangladesh and Thailand. There is an increased flood risk for habitations on the deltas influenced by both riverine and coastal drivers of flooding (Szabo et al., 2016a), globally exposing 9.3% more people annually to riverine flooding than otherwise estimated without the compounded influence (Eilander et al., 2020). Simultaneously, SLR and subsidence are also expected to increase the risk due to frequent flood events for these delta regions than the longer-return periods otherwise associated with SLR (Yin et al., 2020).

10.4.6.3.7 Permafrost thawing and associated risks

In Northern Eurasia, observed and projected climate change impacts are especially pronounced. On land, the presence of permafrost, which occupies substantial areas of eastern Russia, Mongolia and mountain regions of China, creates specific challenges for economic development and human activities. By 2050, it is *likely* that 69% of fundamental human infrastructure in the Pan Arctic will be at risk (RCP 4.5 scenario), including more than 1200 settlements (Hjort et al., 2018). Majority of population and absolute majority (85%) of large settlements on permafrost are located in Russia and 44% of those are expected to be profoundly affected by permafrost thaw by 2050 (Streletskiy et al., 2019; Ramage et al., 2021). Under RCP8.5, climate-induced decrease of bearing capacity and, in regions with ice-rich permafrost, thaw subsidence, is projected to affect 54% of all residential buildings on permafrost with combined worth of $20.7 billion USD; 20% of commercial and industrial structures and 19% in critical infrastructure with a total worth of $84.4 billion USD (Streletskiy, 2019). Transport infrastructure in Russia and China are impacted by thaw subsidence and to lesser degree from frost heave, which add significant operational costs and limit accessibility of remote settlements (Ni et al, 2021; Porfiriev et al., 2019).

Especially in Russia, significant populations and fixed infrastructure assets are located in urban centers on permafrost that is degrading significantly. Two major risks associated with permafrost degradation are loss of permafrost bearing capacity and ground subsidence (Streletskiy et al., 2015). The former determines the ability to support foundations of buildings and structures and is a vital characteristic of sustainability of the economic centers, while the latter impacts the ability of critical infrastructure (roads, railroads) to provide transportation and support accessibility of remote populations and economic centers on permafrost. Proximity of some settlements to the coasts or areas with uneven topography may further increase risks associated with permafrost degradation as ice-rich coasts characterised by high rates of coastal erosion, while settlements located on slopes may experience higher rates of mass wasting processes.

Observed changes in climate resulted in permafrost warming and increased thaw depth in undisturbed locations (Biskaborn et al., 2019), but in built up areas these transformations were exacerbated by human activities (Grebenets et al., 2012). Norilsk, the largest city built on permafrost above the Arctic Circle (Shiklomanov et al., 2017b) was found to have one of the highest trends of near-surface permafrost warming (Streletskiy et al., 2012). Anomaly high temperatures and earlier snowmelt in 2020 may have contributed to oil storage collapse and resulting spill of 20 thousand tons of diesel fuel in Norilsk area (Rajendan et al., 2021). The ability of foundations to support structures have decreased by 10 to 40% relative to the 1960s in the majority of settlements on permafrost in Russia (Streletskiy et al., 2012) and further expected to decrease by 20 to 33% by 2050-59 relative to 2006-15 (Streletskiy et al., 2019).

10.4.6.3.8 Risks and impacts on infrastructure

South Asia and Africa bear the highest losses from unreliable infrastructure and climate change will increase these losses due to hazards, and necessitate additional infrastructure investments to address new risks (Hallegatte et al., 2019; Lu, 2019)[6]. Specifically, power generation and transport infrastructure incur losses

[6] While Hallegatte et al. (2019) estimate that in low- and middle-income countries, the cost of infrastructure disruptions range from $391-$647 billion, they highlight that "while these estimates are incomplete, they highlight the substantial costs that unreliable infrastructure impose on people in low- and middle- income countries".

of $30 billion a year on average from hazards (about $15 billion each), with low- and middle-income countries shouldering about $18 billion of the total amount (Koks et al., 2019; Nicholls et al., 2019).

Among the top 20 countries that are rapidly expanding their infrastructure stock while facing high disaster risk and low infrastructure quality, Laos, Philippines, Bangladesh, Cambodia, Kyrgyzstan, Bhutan, and Viet Nam are from Asia. (UNISDR, 2017; WEF, 2018). The losses are due to direct damage to infrastructure, disruption in services, and affected supply chains (Hallegatte et al., 2019). East Asia and the Pacific and South Asia have the highest adaptation deficits in coastal protection with USD 75 billion in the former and USD$49 billion in the latter (Nicholls et al., 2019). If overall damages are minimised, low- and middle-income countries may need to invest 0.1 to 0.5 percent of their GDP annually up to 2030 for protection against both coastal and river floods, varying based on level of acceptable risks, construction costs, urbanisation and climate uncertainties[7].

- **Power disruption:** Contrasting with high-income countries such as USA, where hazards, particularly storms, are responsible for 50% of power outages, this share is much lower in countries like Bangladesh or India, because system failures due to non-natural causes are very frequent. However, outages caused by hazards tend to be longer and geographically more widespread than other outages (Rentschler et al., 2019). Climate change induced sea-level is expected to impact power infrastructure even necessitating power plant relocation (Hallegatte et al., 2019). In Bangladesh, to avoid inundations caused by SLR (SSP2, RCP 8.5), approximately one-third of power plants may need to be relocated by 2030; an additional 30 percent power plants are *likely* to be affected by increased salinity of cooling water and increased frequency of flooding, while the northern region power plants will probably see a decrease in output because of droughts (Hallegatte et al., 2019). In 2013 in Chittagong (Pervin et al., 2020), users experienced about 16 power outages due to storms alone (Hallegatte et al., 2019). Further, low-carbon technology diffusion might make certain infrastructures redundant, leading to stranded assets.

  Across Asia, infrastructure impacts are mixed: net importers such as China and India will see GDP gains while extreme examples include Russia, a net exporter, which could see steep declines in fossil fuel production (Mercure et al., 2018). In low- and middle-income countries globally, disruption in power supply can impact firms directly (up to USD 120 billion per year), with coping costs (up to USD 65 billion a year), and other indirect impacts. Similarly, for households, the direct impact and cost of coping could be between USD 2.3 – 190 billion per year. Although all power outage is not due to natural hazards, there is a significant number that is attributed to disasters. Besides, outages caused by natural hazards tend to be longer and geographically larger than other causes (Hallegatte et al., 2019).

- **Transportation disruption:** Of the 20 countries in which the road and railway infrastructure is expected to be most affected in absolute terms due to multi-hazards, half are Asian (Koks et al., 2019). In low- and middle-income countries globally, the direct losses to firms on account of transportation disruption are about USD$107 billion per year, excluding the costs due to sales losses or delayed supplies and deliveries alone (Hallegatte et al., 2019). In the transport sector, floods and other hazards disrupt traffic and cause congestion, taking a toll on people and firms in rich and poor countries alike.

- **Water supply and disposal infrastructure disruption**: In low- and middle-income countries, disruption of water supply could lead to direct losses of about $6 billion per year to firms, and between $88 billion - $153 billion a year for households (willingness to pay to avoid disruption). Additionally, there are second order costs associated with finding alternate sources of water and health issues (of the order 6-9 billion USD per year accounting for medical bills and missed income) (Hallegatte et al., 2019). In China, climate models project that increasing number of wastewater treatment plant assets face climate-induced flood hazards in both the near and far future, potentially affecting as many as 208 million users by 2050 (Hu et al., 2019).

[7] Estimates based on the DIVA model that uses SSP 2, 3 and 5 and RCP 2.6, 4.5 and 8.5 in Nicholls et al. (2019) and investments from Ward et al. (2017). According to this study, uncertainty regarding socioeconomic changes and climate change is small compared with the uncertainty around construction costs and tolerance to risk.

Figure 10.8: Risks and key adaptation options in select cities across Asia. Cities were chosen to ensure coverage of different sub-regions of Asia, represent different risk profiles, different city sizes (based on current population and projected growth) and reported progress on different adaptation strategies (infrastructural, institutional, ecosystem-based, and behavioural). Full line of sight in SM10.4.

10.4.6.4 Adaptation in cities across Asia

A review of urban adaptation in South, East and Central Asia found examples of 180 adaptation activities across 74 cities (Dulal, 2019). Most adaptation actions in Asia are in initial stages (Araos et al., 2016) with more (57%) focus on preparatory actions such as capacity building and vulnerability assessment and 43% implemented adaptation (see also SM10.4). Most adaptation actions were focused on disaster risk management (Dulal, 2019) though proportion of climate finance spent on disaster preparedness is not very high (as (Georgeson et al., 2016) show in megacities of Beijing, Mumbai, and Jakarta). Although key port cities across Asia are at high risk from climate impacts, it is estimated that adaptation interventions constitute only a small proportion of cities' climate efforts (Blok and Tschötschel, 2015).

Critically, most urban adaptation in South, East and Central Asia were reactive in nature (Dulal, 2019) (Singh et al., 2021b), raising questions on preparedness, proactive building of adaptive capacities, and whether present actions can lock certain cities/sectors into maladaptive pathways (Friend et al., 2014; Gajjar et al., 2018) (Salim et al., 2019) (Chi et al., 2020). China, India, Thailand, and Republic of Korea record the most number of urban adaptation initiatives, driven mainly by supportive government policies (Lee and Painter, 2015; Dulal, 2019). The number of actors working on urban adaptation is growing: in addition to national governments and local municipalities, civil society, private sector actors (Shaw, 2019), and transnational municipal networks (Fünfgeld, 2015) are emerging as important for knowledge brokering, capacity building, and financing urban adaptation (Karanth and Archer, 2014; Chu et al., 2017; Bazaz et al., 2018).

Adaptation options include (1) infrastructural measures such as building flood protection measures and sea walls, and climate-resilient highways and power infrastructure (Shaw et al., 2016b; Ho et al., 2017); (2) sustainable land use planning through zoning, developing building codes (Knowlton et al., 2014; Nahiduzzaman et al., 2015; Rahman et al., 2016; Ahmed et al., 2019b); (3) ecosystem-based adaptation measures such as protecting urban green spaces, improving permeability, mangrove restoration in coastal cities etc. (Brink et al., 2016; Fink, 2016; Yu et al., 2018d), (4) relocation and migration out of risk-prone areas (McLeman, 2019; Hauer et al., 2020; Maharjan et al., 2020); and (5) disaster management and contingency planning such as through early warning systems, improved awareness and preparedness measures (Shaw et al., 2016a). Asian cities are also focusing on institutional adaptation measures which cut across the five categories mentioned above such as through building capacity and local networks (Anguelovski et al., 2014; Friend et al., 2014; Knowlton et al., 2014), improving awareness (Knowlton et al., 2014), and putting local research and monitoring mechanisms in place (Lee and Painter, 2015) to enable adaptation.

10.4.6.4.1 Infrastructural adaptation options

The challenge of adapting infrastructure to climate change is two-fold: there are significant infrastructure deficiencies, especially in low income countries across Asia, and key infrastructures are at high risk due to climate change (Hallegatte et al., 2019; Lu, 2019). Infrastructural adaptation options in cities attempt to enable networked energy, water, waste, and transportation systems to prepare for and deal with climate risks better (Meerow, 2017) through interventions such as improved highways and power plants, climate-resilient housing, and improved water infrastructure, etc. (ADB, 2014).

- **Power infrastructure**: Adaptations in electricity systems include climate resilient power infrastructure, particularly essential for coastal megacities such as Manila, Mumbai, Bangkok, Ho Chi Minh City (Meerow, 2017; Duy et al., 2019), which double as regional economic hubs and are home to tens of millions of people within Asia. In the Philippines, solar panels at water pumping stations are installed to operate and maintain a minimal capacity to pump water if the electricity grid were to break down (Stip et al., 2019).

- **Water infrastructure:** Sustainable water supply and resource management are key to urban adaptation through improved water service delivery, wastewater recycling, and storm water diversion (Deng and Zhao, 2015; Xie et al., 2017; Yu et al., 2018d). Infrastructure-based adaptation options in urban water management include building water storage facilities, storm water management, and enhancing water quality improving permeability, managing runoff, and enabling groundwater recharge. One example is of Shanghai (China), where infrastructural and policy incentives come to together to enable adaptation: the city has been divided into 14 water conservancy zones, including 348 polder areas with 2517 km of dykes, 1499 pump stations, and 2203 sluices (Yu et al., 2018d). It also depends on a regional inundation control system, flood early warning system, and emergency plan to deal with flood risk and mitigate waterlogging (Chen et al., 2018e; Yu et al., 2018d). Another example is Ho Chi Minh City (Viet Nam), where, given significant increases in area at risk of flooding under climate change, the city has invested in storm sewer upgradation, dike works, improving drainage, and increasing height of road embankments and minor bridges (Storch and Downes, 2011; ADB, 2014; Ho et al., 2017). These infrastructural interventions were complemented by designing an early warning system to initiate flood mitigation procedures, such as isolating critical electrical and mechanical operating systems from water.

- **Built infrastructure**: Current built infrastructure adaptation interventions are mostly reactive (e.g., strengthening housing units, using sandbags during flooding, storing of food, evacuation) rather than preventive (e.g., relocation, building multi-storey and stronger housing units), mainly due to limited resources within most vulnerable households for investing in proactive measures (Francisco and Zakaria, 2019). For cities in North Asia seeing permafrost thawing, adequate land-use practices, permafrost monitoring, maintenance of infrastructure and engineering solutions (e.g. using thermosiphons) may temporarily offset negative effects of permafrost degradation in small, economically vital areas, but are *unlikely* to have an effect beyond the immediate areas (Shiklomanov et al., 2017b; Streletskiy, 2019). Importantly, thawing permafrost and GHG emissions create feedbacks where emissions amplify warming and drive additional thaw. Reducing these impacts through mitigation will reduce the need for adaptation significantly (Schaefer et al., 2014).

- **Infrastructure and technology:** Several infrastructural options employ technology such as smart meters to monitor water usage, technology-based service delivery but these are differentially adopted across Asian sub-regions with higher adoption across East Asia. Examples include the Yokohama smart city project in Japan, which has been smart eco-urbanism interventions since 2011 (e.g. energy saving and storage infrastructure, wastewater management, behavioural change towards renewable energy and low-carbon transportation) (IUC, 2019); the Tianjin Eco-city mega-project in China, which is testing a range of measures to meet urban sustainability goals in partnership with Singapore (ICLEI, 2014b; Blok and Tschötschel, 2015), development in New Songdo (Republic of Korea) which is experimenting with interventions such as embedded smart waste management (Anthopoulos, 2017), and national policy initiatives such as the Smart Cities Mission covering 100 cities in India (e.g. technology-enabled water, energy, and land management for urban agriculture in Nashik city) (ICLEI, 2014a). However, the efficacy of such measures, especially for larger sustainability and climate change goals remain to be seen (ICLEI, 2014b; ICLEI, 2014a; Caprotti et al., 2015; Anthopoulos, 2017).

Infrastructural measures alone are seldom effective in building urban resilience as seen in the examples of 2011 floods in Bangkok and 2005 typhoon in Manila (Duy et al., 2019) or projected estimates by Pervin et al. (2020) who find that structural interventions in existing drainage systems reduce flooding risk by 7-19% in Sylhet (Bangladesh) and Bharatpur (Nepal) but without proper solid waste management, area under flood risk could increase to 18.5% in Sylhet and 7.6% in Bharatpur in five years, rendering the infrastructural interventions ineffective over time. While in some cities, it is estimated that infrastructural adaptation through 'hard' flood protection strategies (e.g. storm-surge barriers and floodwalls) is more effective than institutional or ecosystem-based adaptation by 2100 (e.g.Du et al.in Shanghai), a hybrid approach where hard strategies protect from flood risk and soft strategies reduce residual risk from hard strategies is suggested (Du et al., 2020). In Japan, without adaptation, estimated damage costs of floods (caused by tropical cyclones, altered precipitation), by 2081-2100 under RCP2.6 will be 28% higher (compared to 1981-2000), rising to 57% higher under RCP8.5 (Yamamoto et al., 2021). With a combination of adaptation measures (such as land use control, piloti building, flood control measures), estimated damage costs can be reduced even below 1981-2000 levels and with a combination of mitigation and these adaptation measures, an estimated 69% reduction in flood damage costs are expected; demonstrating the importance of concerted and immediate climate action in reducing damage.

Infrastructural interventions can sometimes be maladaptive when assessed over longer time periods; e.g. the Mumbai Coastal Road (MCR) project aimed at reducing flood risk and protecting against SLR will potentially cause damages to intertidal fauna and flora and local fishing livelihoods (Senapati and Gupta, 2017); Jakarta's Great Garuda project aimed at reducing flood risk is expected to *increase* flood risk for the poorest urban dwellers (Salim et al., 2019).

Figure 10.9: Effectiveness of select adaptation options in cities across Asia. Effectiveness is assessed based on the option's ability to reduce risk as reported in the literature.

10.4.6.4.2 Sustainable land use planning and regulation

Land use in cities impacts resource use (e.g. water, energy), risk (a function of population density, service provision, hazard exposure), and adaptive capacity, all of which influence efficacy of urban adaptation (de Coninck et al., 2018). Locally-suited land use planning and regulation (such as appropriate zoning or building codes, safeguarding land rights) can have adaptation co-benefits (Mitchell et al., 2015; Dhar and Khirfan, 2016), e.g. strict building regulations can protect urban wetlands and associated ecosystem services (Jiang et al., 2015); appropriate land zoning can safeguard green spaces, ensure improvements in permeability, and avoid new development in risk-prone locations (Duy et al., 2019); ensuring tenurial security or regularizing informal settlements can incentivise improvements to housing quality, thereby alleviating vulnerability of the most marginal (Mitchell et al., 2015).

Land tenure arrangements strongly shape urban dweller's vulnerability and their adaptive capacities (Roy et al., 2013; Michael et al., 2018). For example, in Khulna, Roy et al. (2013) find significant differences between the adaptive strategies of house owners and renters in low income settlements, a finding echoed in Bangalore (India) (Deshpande et al., 2018) and Phnom Penh (Cambodia) (Mitchell et al., 2015). In Riyadh (Saudi Arabia), land-based adaptation strategies include land zoning to control population and building density, demarcating environmental protection zones, and sub-urbanisation (Nahiduzzaman et al., 2015; Rahman et al., 2016). In many Asian cities, land subsidence control can serve as an adaptation strategy since it is estimated to significantly reduce relative sea-level rise (*high confidence*). This has an important implication in that subsidence control would be a good and a complementary measure to climate mitigation and climate adaptation in many coastal urban settings in Asia (Cao et al., 2021; Nicholls et al., 2021). Urban land use planning, if used proactively, can incentivise adaptation-mitigation synergies and avoid unintended negative consequences of urbanisation as Xu et al. (2019) show in Xiamen.

10.4.6.4.3 Ecosystem-based adaptation

The literature on urban Ecosystem-based Adaptation (EbA)[8], especially across Asia, has grown significantly since AR5 (Demuzere and al., 2014; Yao et al., 2015; Brink et al., 2016; Bazaz et al., 2018; de Coninck et

[8] Ecosystem-based Adaptation (EbA) is defined by IPBES as the conservation, sustainable management and restoration of natural ecosystems to help people adapt to climate change (Glossary, 2019). In urban areas, EbA includes improving ecological structures (e.g. maintaining watersheds, forests, green roofs), ecological functions and processes (e.g. wetland functioning for flood protection), valuation measures (including monetary or non-monetary values to ecosystem service benefits), and investing in ecosystem management practices (i.e. enabling adaption co-benefits through the maintenance, preservation, restoration or creation of ecological structures) (Liu et al., 2014a; Brink et al., 2016). Thus, EbA adaptation actions include protecting urban green spaces, improving permeability, fostering urban

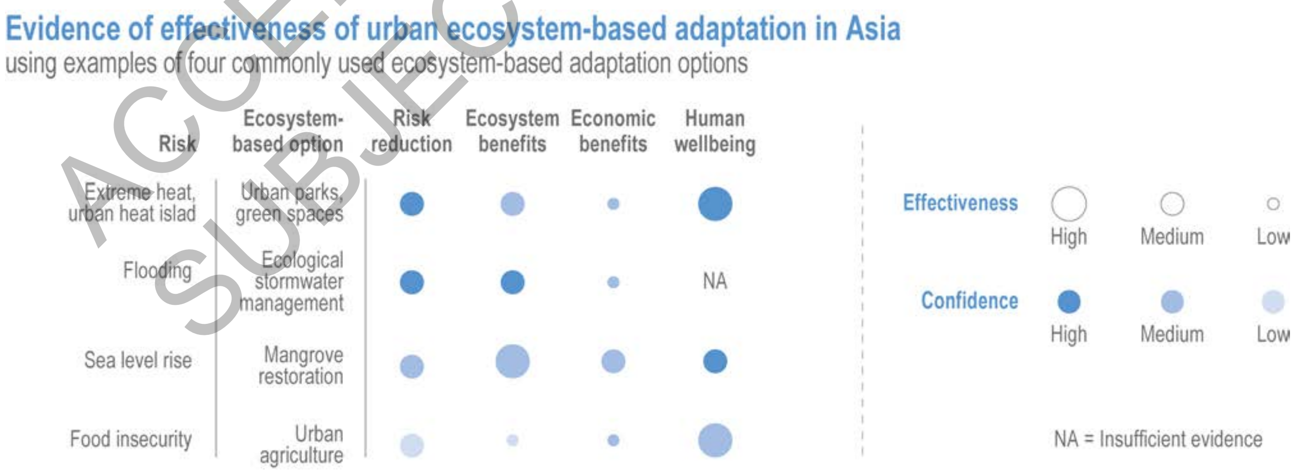
al., 2018; Ren, 2018). This growing literature reflects the wide recognition that infrastructural adaptation can often have ecological and social trade-offs (Palmer et al., 2015) and need to be complemented by ecosystem-based actions to manage risk more effectively (Du et al., 2020), build adaptive capacity, and in some cases, meet mitigation and sustainable development goals (Huang et al., 2020).

Illustrative examples of EbA in Asian cities include sponge cities in China for sustainable water management, flood mitigation, and minimising heat waves impact (Jiang et al., 2018; Yu et al., 2018d; Wang et al., 2019a; Zhanqiang et al., 2019), Singapore's Active, Beautiful, Clean Waters (ABC Waters) Programme, which uses bio-engineering approaches to protect river channels and prevent localised flooding, improve water quality, and create community spaces, and Dhaka's green roofs and urban agriculture (Zinia and McShane, 2018).

EbA approaches to manage floods, capture and store rainwater, restore urban lakes and rivers, and reduce surface run-off often blend infrastructural and ecosystem-based approaches. For example, in Tokyo (Japan), stormwater management is done by sophisticated underground infrastructure and an artificial infiltration stormwater system (Saraswat, 2016) (Mishra et al., 2019). China's Sponge City Program aims to reduce the impacts of flooding through low-impact development measures, urban greenery, and drainage infrastructure, such that 80 percent of urban areas reuse 70 percent of rainwater by 2020, which would help ensure the resilience of these cities to floods (Li et al., 2016b; Stip et al., 2019).

Case studies on urban EbA also raise equity concerns (*medium evidence, medium agreement*) such as interventions biased towards suburban areas in Guangzhou (China) (Zhanqiang et al., 2019); inadequate consideration of low-income, vulnerable populations (Blok and Tschötschel, 2015; Meerow, 2017) (Mabon and Shih, 2021); and low familiarity with interventions such as artificial wetlands, water retention ponds, green façade/walls can restrict inclusiveness (Zinia and McShane, 2018). Further, urban EbA is constrained by a range of factors such as inadequate institutional structures and processes for connecting different remits and knowledge systems and tradeoffs in landuse for different purposes (Mabon and Shih, 2021; Singh et al., 2021b).

EbA interventions are not uniform across Asian cities: in a global study on urban EbA, Brink et al. (2016) find Eastern Asia, India and Israel report most EbA interventions and there is variable and *limited evidence* on effectiveness and scalability (SM10.5). Using a risk framing (i.e. the extent to which an option reduces risk), urban EbA options in Asian cities score as being 'low to medium' effective (See SM10.5). However, when the assessment is expanded to assess the ecosystem benefits, economic impacts, and human wellbeing co-benefits of EbA, effectiveness increases. Figure 10.10 shows the evidence of effectiveness of EbA.



agriculture, mangrove restoration in coastal cities, improved wetland management, etc. (Doswald et al., 2014; Brink et al., 2016; de Coninck et al., 2018).

Figure 10.10: Evidence on effectiveness of ecosystem-based adaptation using examples of four commonly used EbA options[9]. Effectiveness is assessed qualitatively based on the evidence (for full line of sight see SM10.5) and is examined through four framings: potential to reduce risk (e.g. reduced exposure to hazard; reduced risk); benefits to ecosystems (through improved ecosystem health, high biodiversity); economic benefits (e.g. improved incomes, fewer man-days lost, better livelihoods); and human wellbeing outcomes (e.g. health, quality of living etc.). Darker shading signifies high effectiveness while lightest shade signifies low effectiveness of an EbA option (i.e. the option scores low on the indicator).

For example, urban agriculture is identified as offering multiple benefits such as mitigating emissions associated with food transportation from rural to urban areas, improving food and nutritional security, strengthening local livelihoods and economic development, improved microclimate, soil conservation, improved water and nutrient recycling, efficient water management (Padgham and Dietrich, 2015; Patil et al., 2019) but can potentially undermine ecosystem services through land use changes, water over-extraction or applying chemical fertilisers (Ackerman et al., 2014), expose smallholders to volatile markets and crops that are not consumed by farming households themselves, thus undermining food security, or increasing work burdens on women, and health externalities – e.g. through use of untreated wastewater, or rearing poultry and livestock in unsanitary conditions. There remain gaps on understanding the differential impacts of urban agriculture at different scales as well as its effectiveness in improving adaptive capacity at scale.

10.4.6.4.4 Migration and planned relocation

There is *medium evidence* with *high agreement* that climatic risks are exacerbating internal and international migration across Asia (IDMC, 2019) (Maharjan et al., 2020) **[Box 10.2].** In coastal cities, formal 'retreat' measures such as forced displacement and planned relocation (Oppenheimer et al., 2019) are commonly considered 'last resort' adaptation strategies once other infrastructural and ecosystem-based protect and accommodate strategies are exhausted (Haasnoot et al., 2019) (CCP 2.3). In contrast, migration (which can take various forms from seasonal, temporary mobility to circular or permanent movement), is a regular feature across Asian urban settlements (Maharjan et al., 2020)[Also see Box 10.2; MIGRATION CCB].

There is *robust evidence* (*medium agreement*) that across Asia, migration (and increasingly planned relocation) will continue to be a key risk management strategy, especially in low lying flood-prone cities (e.g. in SE and South Asia) and across drylands (e.g. in South and Central Asia) (Davis et al., 2018) (Ajibade, 2019) (Lincke and Hinkel, 2021). While there is insufficient evidence to project migration numbers under different warming levels, it is well established that migration as an adaptation strategy is not equally available to all (Ayeb-Karlsson, 2020) and climatic risks might reduce vulnerable populations' ability to move due to losses of assets, thus reinforcing existing inequalities and differential adaptive capacities (Singh and Basu, 2020);(Zickgraf, 2019) (Blondin, 2019; Cundill et al., 2021; Gavonel et al., 2021).

There is *medium evidence* (*low agreement*) about the effectiveness of migration and planned relocation in reducing risk exposure. Evidence on climate-driven internal migration shows that moving has mixed outcomes on risk reduction and adaptive capacity. On one hand, migration can improve adaptive capacity by increasing incomes and remittances as well as diversifying livelihoods (Maharjan et al., 2020). On the other, migration can expose migrants to new risks. For example, in Bangalore (India), migrants often face high exposure to localised flooding, insecure and unsafe livelihoods, and social exclusion, which collectively shape their vulnerability (Byers et al., 2018);(Singh and Basu, 2020). In Metro Manila (Philippines) and Chennai (India), planned relocations to reduce disaster risk have often exacerbated vulnerability, due to relocation sites being in environmentally sensitive areas, inadequate livelihood opportunities, and exposure to new risks (Ajibade, 2019; Jain et al., 2021) (Meerow, 2017).

10.4.6.4.5 Disaster management and contingency planning

There is rich case-based evidence across Asia on urban adaptation to extreme events with relatively more evidence on rapid-onset events such as cyclones and flooding than slow-onset disasters such as drought (Ray and Shaw, 2019; UNESCAP, 2019); (Singh et al., 2021a) see Box 10.7 on Loss and Damage). Overall, there

[9] Assessing effectiveness of adaptation actions is challenging because of the lack of a clear goal that signifies effective adaptation, varied conceptual framings and metrics used to assess effectiveness, and low empirical evidence on effectiveness of implemented adaptation actions, (Singh et al., 2021a);(Owen, 2020).

has been a growing emphasis on 'build back better' interventions (Mannakkara and Wilkinson, 2013); (Hallegatte et al., 2018) that approach disaster management holistically through infrastructural solutions such as climate-resilient housing or sea walls and soft approaches such as strengthening livelihoods, developing early warning systems (EWS)[10], increasing awareness about disaster risks and impacts, and building local capacities to deal with them (Bhowmik et al., 2021). Notably, urban disaster management is effective when land use planning processes including greenfield development, zoning and building codes, and urban redevelopment are leveraged to reduce and/or avoid risk, thereby averting potential maladaptation (Kuhl et al., 2021).

There is relatively lower empirical evidence on how microenterprises and businesses are adapting to increased risk but recent examples in Mumbai, India (Schaer and Pantakar, 2018) and Kratie, Cambodia (Ngin et al., 2020) suggest that businesses primarily adopt temporary and reactive responses rather than long-term, anticipatory adaptation measures.

A review of innovative disaster risk reduction (DRR) approaches notes the use of GIS and drone-based technologies for mapping risk exposure and impacts, mobile-based payments for post-disaster compensation, to transnational initiatives and learning networks on urban resilience (Izumi et al., 2019). Further, technology-based innovations such as using big data (Yu et al., 2018b), improved warnings through mobile phones, or mobilising relief through social media (Carley et al., 2016) are proving effective for disaster preparedness, relief and recovery. Community-based DRR is consistently ranked as most effective for its role in transforming DRR towards being more context-relevant and inclusive. Ecosystem-based disaster risk reduction (EbDRR) is also gaining prominence and includes strategies such as mangrove plantation and rejuvenation in vulnerable coastal areas. Nature-based solutions for flood protection and reducing drought incidence have emerged as an alternative to costlier 'hard' infrastructure (Rozenberg and Fay, 2019); (UN-Water, 2018); (Zevenbergen et al., 2018). Some cities are also reporting adaptation to heat risk. For example, Ahmedabad (India) has pioneered preparedness for extreme temperatures and heat waves by developing annual Heat Action Plans, building regulations to minimise trapping heat, advisories about managing heat stress, and instituting cool roofs policy (Ahmedabad Municipal, 2018).

Financing, regulations, and institutional processes have a significant role to play in incentivising disaster risk reduction and resilience in large-scale city-level built infrastructure by the private sector and other actors. Currently there are gaps in these mechanisms, leading to infrastructure development in disaster-prone areas, increasing exposure to people, property, economy and systems (Jain, 2013). Both firms and governments need to take disaster risks into consideration in supply-chain management to avoid disruptions and subsequent negative effects (Abe and Ye, 2013). There are several institutional challenges faced during DRR and CCA implementation including overlapping efforts and inefficient use of scarce resources due to inappropriate funding mechanisms, a lack of coordination and collaboration, a lack of implementation and mainstreaming, scale mismatches, poor governance, the socio-political-cultural structure, competing actors and institutions, lack of information, communication, knowledge sharing, and community involvement, and policy gaps (Seidler et al., 2018; Islam et al., 2020).

10.4.6.5 Enabling urban adaptation across Asia

There is growing empirical evidence of conditions enabling and constraining urban adaptation (Table 10.3) with relatively more literature from South, South East, and East Asia. Governance and capacity-related deficits are repeatedly identified as significant barriers to urban adaptation (*robust evidence, high agreement*) and interact with financial and informational constraints to mediate adaptation action.

[10] The set of technical, financial and institutional capacities needed to generate and disseminate timely and meaningful warning information to enable individuals, communities and organisations threatened by a hazard to prepare to act promptly and appropriately to reduce the possibility of harm or loss. Dependent upon context, EWS may draw upon scientific and/or Indigenous knowledge. EWS are also considered for ecological applications e.g., conservation, where the organisation itself is not threatened by hazard but the ecosystem under conservation is (an example is coral bleaching alerts), in agriculture (for example, warnings of ground frost, hailstorms) and in fisheries (storm and tsunami warnings). (IPCC, 2018a)

Table 10.3: Barriers and enablers to adaptation across Asian cities.

Indicator	As an enabler	As a barrier
Governance and planning	**National policy directives** to adapt. e.g. strong national climate commitments in China, India, and Thailand (Dulal, 2019); and dedicated public-private councils on climate change in Seoul, Republic of Korea (Lee and Painter, 2015). Participatory planning, **co-producing solutions**, and engaging multiple stakeholders. E.g. Surat (Anguelovski et al., 2014; Karanth and Archer, 2014; Chu et al., 2017), Guwahati (Archer et al., 2014) in India; Bandar Lampung and Semarang in Indonesia (Archer et al., 2014); Seoul in Republic of Korea (Lee and Painter, 2015) **Devolving decision-making** to city governments (ADB, 2013) and strong **political leadership** helps institutionalising adaptation programs (Anguelovski et al., 2014; Friend et al., 2014; Lee and Painter, 2015), e.g. in Moscow (Russia) where the city mayor has spearheaded climate action (van der Heijden et al., 2019) **Mainstreaming climate adaptation** in city plans (UN-HABITAT and UNESCAP, 2018)	**Low accountability and transparency** in planning processes with inadequate spaces for public dialogue (Friend et al., 2014) and limited accountability to the most economically and politically marginalised people within cities (Garschagen and Marks, 2019). 65% of 180 urban adaptation interventions across Asia are **reactive** in nature (Dulal, 2019) thus missing opportunities for risk prevention and preparedness (Francisco and Zakaria, 2019). **Lack of forward-looking, learning-oriented processes** constrain adaptation with short-term development priorities often overshadowing long-term climate action needs (Friend et al., 2014; de Leon and Pittock, 2017; Gajjar et al., 2018; Khaling et al., 2018) (Garschagen and Marks, 2019; Jain et al., 2021). **Fragmented governance, lack of mainstreaming** between CCA and DRR (Fuhr et al., 2018; Khaling et al., 2018) E.g. in Vietnam, Thailand, Indonesia (Friend et al., 2014) and Metro Manila (Philippines) (Meerow, 2017)
Information	Knowledge sharing through **transnational municipal networks** such as C40, ACCRN, A-PLAT (Fünfgeld, 2015) City-level knowledge creation and knowledge transfer institutions (Lee and Painter, 2015)	**Data gaps** on projected climate risks and impacts in certain sub-regions and small settlements (Revi et al., 2014) **Numerous tools** for assessing vulnerability, adaptation planning (Nordgren et al., 2016)
Technology, infrastructure	Early warning systems, climate information, modelling studies inform adaptation decision-making (Reed et al., 2015; Singh et al., 2018a)	Inadequate **regional downscaled data** at city-scale (ADB, 2013; Khaling et al., 2018) Inadequate **cost benefit analyses** of different adaptation strategies (Khaling et al. 2018)
Capacity and awareness	A focus on **learning, experimentation, awareness and capacity building**, leads to more sustained, legitimate, and inclusive adaptation (ADB, 2013; Anguelovski et al., 2014); Reed et al. (2015)_	Limited access and capacity to use risk assessment tools (ADB, 2013; Shaw et al., 2016b)
Finance	**Dedicated adaptation financing**. E.g. in Beijing, adaptation spending is 0.33% of city's GDP (Georgeson et al., 2016); steering international and local funding to leverage adaptation benefits in urban development programs such as in Surat (India) (Cook and Chu, 2019); mainstreaming climate adaptation into development programming to leverage developmental finance for adaptation action (Cuevas et al., 2016; Narender and Sethi, 2018).	Inadequate **adaptation funding**, lack of **financial devolution** to city governments (Fuhr et al., 2018) (Garschagen and Marks, 2019).

10.4.7 Health and Wellbeing

Climate change is increasing risks to human health in Asia by increasing exposure and vulnerability to extreme weather events such as heat waves, flooding and drought, air pollutants, increasing vector-borne and water-borne diseases, undernutrition, mental disorders and allergic diseases (*high confidence*). Sub-regional diversity in socio-economic and demographic context (e.g., aging, urban vs agrarian society, increasing population vs reduced birth rate, high income vs low to middle income) and geographical characteristics largely define the differential vulnerabilities and impacts within countries in Asia (*high confidence*).

10.4.7.1 Observed Impacts

High temperatures affect mortality and morbidity in Asia (*high confidence*). In addition to all-cause mortality (Dang et al., 2016; Chen et al., 2018e), deaths related to circulatory, respiratory, diabetic (Li et al., 2014b) and infectious disease (Ingole et al., 2015), as well as infant mortality (Son et al., 2017) are increased with high temperature (*high confidence*). Increased hospital admissions (Giang et al., 2014; Lin et al., 2019) and ambulance transport (Onozuka and Hagihara, 2015) coincide with increased ambient temperature (*high confidence*). Heat waves are particularly detrimental to all-cause and cause-specific mortality (Chen et al., 2015a; Lee et al., 2016; Guo et al., 2017b; Yin et al., 2018). Both rural and urban populations are vulnerable to heat-related mortality (Ma et al., 2015; Chen et al., 2016a; Wang et al., 2018a). Individuals with lower degrees of education and socio-economic status, older individuals and individuals living in communities with less green space are more susceptible to heat-related mortality (*high confidence*) (Yang et al., 2012a; Huang et al., 2015b; Seposo et al., 2015; Son et al., 2016; Kim and Kim, 2017). These heat effects have been attenuating over recent decades in East Asian countries, although the driving force behind this remains unknown (*high confidence*) (Chung et al., 2017c; Chung et al., 2018).

Rising ambient temperatures accelerates pollutant formation reactions and may modify air-pollution related health effects (*medium confidence*). Higher temperatures are associated with increased effects of ozone on mortality (Shi et al., 2020). Climate change causes intensified droughts and greater wind erosion resulting in increased intensity and frequency of sand and dust storms (Akhtar et al., 2018). Mortality and hospital admissions for circulatory and respiratory diseases are increased after exposures to Asian dust events (*high confidence*) (Hashizume et al., 2020). El Niño has a major influence on weather patterns in various regions. For example, it causes dry conditions that sometimes result in forest fires and trans-boundary haze that increased all-cause mortality in children by 41% in Malaysia (Sahani et al., 2014).

Ambient temperature is associated with the risk of an outbreak of mosquito-borne disease in South and Southeast Asia (*high confidence*) (Servadio et al., 2018). Warmer climates are associated with a higher incidence of malaria (Xiang et al., 2018). Moderate rainfall also promotes malaria infection, while excessive rainfall decreases the risk of malaria (Wu et al., 2017b). El Niño intensity is positively associated with malaria incidence in a single year in India (Dhiman and Sarkar, 2017). The duration and survival rate of dengue mosquito development, mosquito density, mosquito biting activity, mosquito spatiotemporal range and distribution, and mosquito flying distance are all affected by temperature (*high confidence*) (Li et al., 2018b). Temperature, precipitation, humidity and air pressure are major weather factors associated with dengue fever transmission (*high confidence*) (Sang et al., 2014; Choi et al., 2016; Xu et al., 2017).

Climate change alters the hydrologic cycle by increasing the frequency of extreme weather events such as excess precipitation, storm surges, floods and droughts (*high confidence*). Water-borne diseases such as diarrhea, leptospirosis and typhoid fever can increase in incidence following heavy rainfall, tropical cyclones and flooding events (*high confidence*) (Deng et al., 2015; Levy et al., 2016; Li et al., 2018b; Matsushita et al., 2018; Zhang et al., 2019b). Droughts can cause increased concentrations of pathogens, which overwhelm water treatment plants and contaminate surface water. A positive association between ambient temperature and bacterial diarrhea has been reported, compared with a negative association with viral diarrhea (Carlton et al., 2016; Wang et al., 2018c).

Asia has the highest prevalence of undenourishment in the world, which was 11.4% in 2017, representing more than 515 million people. Southeast Asia has been affected by adverse climate conditions such as floods and cyclones, with impacts on food availability and prices (FAO, 2018d). Crop destruction due to tropical cyclones can include salt damage from tides blowing inland (*medium confidence*) (Iizumi and Ramankutty, 2015). Sea level rises result in intrusion of saline water into the coastal area of Bangladesh and people living in these areas face an increased risk of hypertension resulting from high salt consumption (Scheelbeek et al., 2016).

Weather conditions have been linked to mental health. High temperatures increase the risk of mental problems including mental disorders, depression, distress and anxiety in Vietnam (Trang et al., 2016), Hong Kong, China (Chan et al., 2018) and Republic of Korea (Lee et al., 2018d). In addition, high temperatures are reported to increase the risk of mortality from suicide in Japan, Republic of Korea, Taiwan, Province of China (Kim et al., 2016c), India (Carleton, 2017) and China (Luan et al., 2019). Extreme weather events such as storms, floods, hurricanes and cyclones increase injuries and mental disorders (post-traumatic stress disorder (PTSD) and depressive disorders) (Rataj et al., 2016), thereby negatively affecting well-being (*high confidence*).

Higher temperatures and increased CO2 elevate the level of allergens such as pollen, which can result in increased allergic diseases, such as asthma and allergic rhinosinusitis. The association between variations in ambient temperature and the occurrence of asthma has been reported in several Asian countries/regions such as Japan (Yamazaki et al., 2015), Republic of Korea (Kwon et al., 2016), China (Li et al., 2016a) and Hong Kong, China (*medium confidence*) (Lam et al., 2016).

10.4.7.2 Projected Impacts

Climate change is associated with significantly increased mortality (*high confidence*). Figure 10.11 shows projected health impacts due to climate change in Asia. The global estimates of excess deaths due to malnutrition, malaria, diarrhea and heat stress are approximately 250,000 deaths per year in 2030-2050 under the medium-high emissions scenario, assuming no adaptation (World Health Organization, 2014). The impacts are expected to be greatest in South, East and Southeast Asia. Another projection showed that the change in heat-related deaths is largest in Southeast Asia, which was 12.7% increase in the end of the century under a high-emission scenario (Gasparrini et al., 2017). As the proportion of older individuals in the population rises, the number of years lost due to disability increases more steeply (Chung et al., 2017b). In the 2080s, the number of annual temperature-related deaths is estimated to reach twice that in the 1980s in China (Li et al., 2018c). Over a 20-year period in the mid-21st century (2041–2060), the incidence of excess heat-related mortality in 51 cities in China was estimated to reach 37,800 (95% CI: 31,300–43,500) deaths per year under RCP8.5 (Bazaz et al., 2018).

Increased concentrations of fine particulate matter and ozone influenced by extreme events such as atmospheric stagnations and heat waves are projected to result in additional 12,100 and 8,900 deaths per year due to fine particulate matter and ozone exposure, respectively in China in the mid-century under RCP4.5 (Hong et al., 2019a). Excess ozone-related future premature deaths is noticeable in 2030 in East Asia and India for RCP8.5 (over 95% of global excess mortality) (Silva et al., 2016).

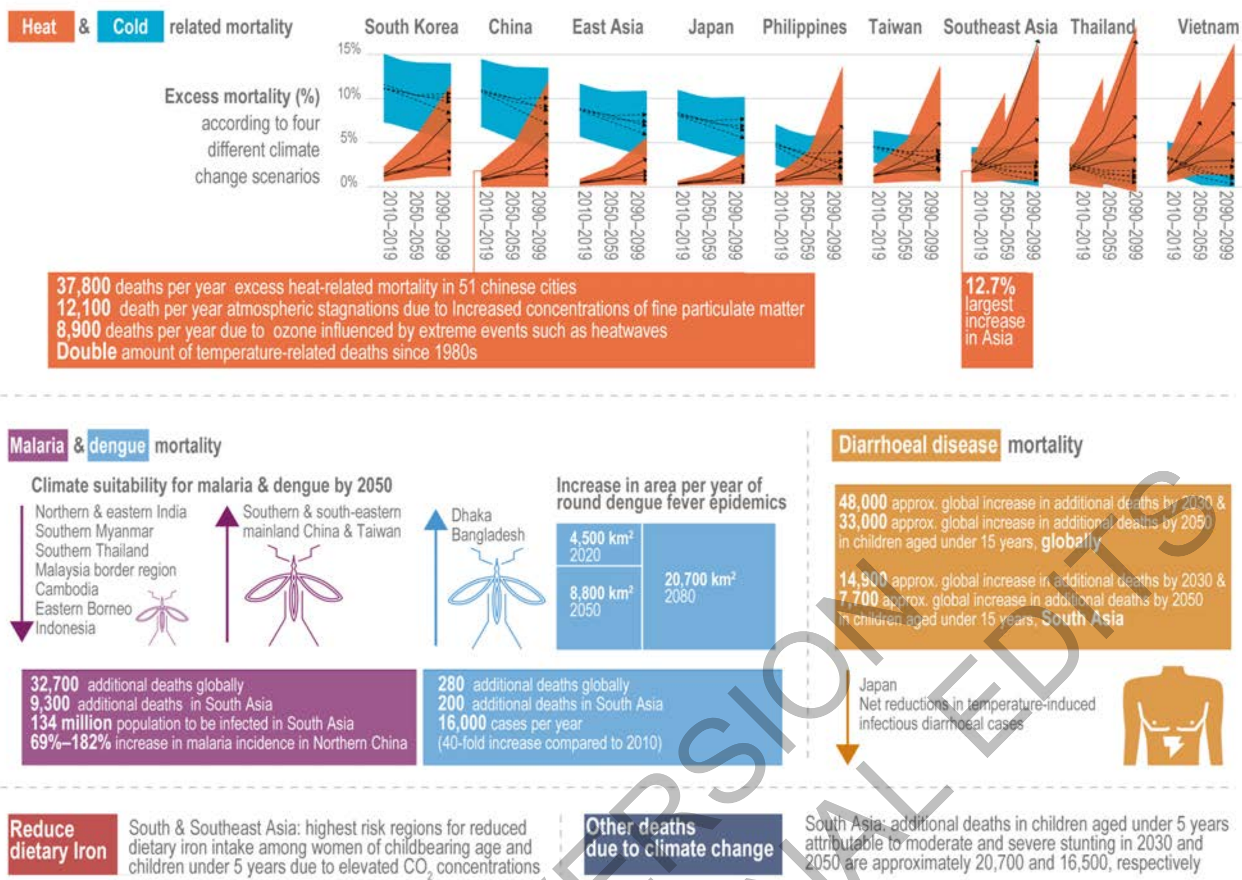


Figure 10.11: Projected health impacts due to climate change in Asia

The global estimates for increases in malaria and dengue deaths (annual estimates) are approximately 32,700 and 280 additional deaths, respectively, in 2050 under the medium-high emissions scenario (World Health Organization, 2014). Among these additional deaths, 9,300 and 200 deaths, respectively, are projected to occur in South Asia. The population at risk of malaria infection is estimated to increase by 134 million by 2030 in South Asia under the medium-high emissions scenario, considering socio-economic development. If no actions are taken, malaria incidence in northern China is projected to increase by 69%–182% by 2050 (Song et al., 2016). Another study suggested a decrease in climate suitability for malaria in northern and eastern India, southern Myanmar, southern Thailand, the Malaysia border region, Cambodia, eastern Borneo and Indonesia by 2050 (Khormi and Kumar, 2016). By contrast, climate suitability for malaria is projected to increase in the southern and south-eastern mainland of China and Taiwan, Province of China (Khormi and Kumar, 2016).

Dengue incidence is projected to increase to 16,000 cases per year by 2100 in Dhaka, Bangladesh, if ambient temperatures increase by 3.3°C without any adaptation measures or changes in socio-economic conditions (Banu et al., 2014). This would represent an increase in incidence of over 40-fold compared with 2010. Higher numbers of dengue fever cases are projected to occur under RCP 8.5 than RCP2.6 in China (Song et al., 2017). Compared with the average numbers in 1997–2012, the annual number of days suitable for dengue fever transmission in the 2020s, 2050s and 2080s will increase by 15, 25 and 40 days, respectively, in south China under RCP8.5. In addition, areas in which year-round dengue fever epidemics occur will *likely* increase by 4500, 8800 and 20,700 km^2 in the 2020s, 2050s and 2080s, respectively, under RCP8.5 (Nahiduzzaman et al., 2015).

The global estimates for increases in deaths due to diarrheal disease (annual estimates) in children aged under 15 years in 2030 and 2050 are approximately 48,000 and 33,000 additional deaths, respectively, under the medium-high emissions scenario (World Health Organization, 2014). Among these additional deaths, 14,900 and 7,700 deaths, respectively, are projected to occur in South Asia. An updated projection with pathogen-specific approach estimated 25,000 additional annual diarrheal deaths in Asia in 2080-2095 under the high emission scenario (Chua et al., 2021), while in some countries such as Japan, net reductions in temperature-induced infectious diarrheal cases were estimated, because viral infections are dominant in these countries during the cold season (Onozuka et al., 2019).

South and Southeast Asia are projected to be among the highest risk regions for reduced dietary iron intake among women of childbearing age and children under 5 years due to elevated CO_2 concentrations (*medium confidence*) (Smith and Myers, 2018). The estimated number of additional deaths due to climate change in children aged under 5 years attributable to moderate and severe stunting in 2030 and 2050 are approximately 20,700 and 16,500, respectively, in South Asia, under the medium-high emissions scenario (World Health Organization, 2014). In Bangladesh, due to climate change, river salinity is projected to be increased in coastal and freshwater fishery communities leading to significant shortages of drinking water in the coastal urban areas (Dasgupta et al., 2014c).

10.4.7.3 Adaptation Options/Co-benefits

The health co-benefits of greenhouse gas mitigation measures in energy generation have been reported to reduce disease burden. In China, the implementation of greenhouse gas policies would reduce the air pollution associated disease burden by 44% in 2020 under the Integrate Carbon Reduction scenario compared with the business as usual scenario (Liu et al., 2017b). Transition to a half-decarbonised power supply for the residential and transport sectors would avoid 55,000-69,000 deaths in 2030 compared with the business as usual scenario (Peng et al., 2018). A shift in travel modes from private motor vehicles to the use of mass rapid transit lines is estimated to reduce CO_2 equivalent emissions by 6% in Greater Kuala Lumpur and bring important health co-benefits to the population (Kwan et al., 2017). The 25 measures developed for reducing air pollution levels in Asia and the Pacific would reduce carbon dioxide emissions in 2030 by almost 20% relative to baseline projections and decrease warming by 0.3°C by 2050 which could eventually reduce heat-related excess deaths in the region (UNEP, 2019). The 25 measures include conventional emission controls focusing on emissions that lead to the formation of fine particulate matter ($PM_{2.5}$), next-stage air-quality measures for reducing emissions that lead to the formation of $PM_{2.5}$ and are not yet major components of clean air policies in many parts of the region, and measures contributing to development priority goals with benefits for air quality. Health co-benefits outweigh mitigation costs in Republic of Korea up to 2050 (Kim et al., 2020). Low-carbon pathways consistent with the 2 ◦C and 1.5 ◦C long-term climate targets defined in the Paris Agreement are associated with the largest health co-benefits when coordinated with stringent air pollution controls in Asia followed by Africa and Middle East (Rafaj et al., 2021).

Strategies to increase energy efficiency in urban built environment by compact urban design and circular economy policies can reduce greenhouse gas emissions and reap ancillary health benefits; compared to conventional single-sector strategies, national CO_2 emissions can be reduced by 15%–36%, and the annual deaths from 25,500 to 57,500 are avoidable from air pollution reduction in 637 Chinese cities (Ramaswami et al., 2017). In a city in China, the existing mitigation policies (e.g., promotion of tertiary and high-tech industry) and the one adaption policy (increasing resilience) increased co-benefits for wellbeing (Liu et al., 2016a).

Changing dietary patterns, particularly reducing red meat consumption and increasing fruit and vegetable consumption, contributes to the reduced greenhouse gas emissions, as well as premature deaths. The adoption of global dietary guidelines was estimated to avoid 5.1 million deaths per year relative to the reference scenario, in which the largest number of avoidable deaths occurred in East Asia and South Asia, and greenhouse gas emissions would be reduced most in East Asia (Springmann et al., 2016). In China, dietary shifts to meet the national dietary reference intakes reduced the daily carbon footprint by 5-28% depending on scenario (Song et al., 2017). In India, the optimised healthy diets (e.g., lower amounts of wheat, and increased amounts of legumes) could help reduce up to 30% water use per person for irrigation and reduce diet-related greenhouse gas emissions. This would result in 6,800 life-years gained per 100,000 population in 2050 (Milner et al., 2017).

10.5 Adaptation Implementation

10.5.1 Governance

10.5.1.1 Points of departure

Climate change governance is characterised by a scalar/stakeholder turn which includes (i) acknowledgement of the importance of both sub-national and transnational-regional scales along with the global scale; (ii) involvement of diverse stakeholders in decision-making systems; (iii) reliance on bottom-up architectures of governance that are supported by the framework given by the SDGs; (iv) emphasis on developmental and environmental co-benefits; (v) recognition of diverse experiences of marginalisation and social stratification, and their impacts on participation in governance-related activities; and (vi) greater decentralisation and strengthening of local institutions.

10.5.1.2 Findings

In order to facilitate local adaption, especially in a context characterised by regional diversity and spatial-temporal variation, climate adaptive governance invites greater policy attention to institution building (formal and informal) at multiple scales and across sectors, (Mubaya and Mafongoya, 2017). Ecosystem-based incremental adaptation (EbA) approach underlines the advantage of drawing upon ecosystem services for reducing vulnerabilities, increasing resilience of communities to adapt to climate change, and minimising threats to social systems and human security, provided climate change remains below 2°C or, better yet, below the 1.5°C of global warming (Barkdull and Harris, 2018).

Focus on multi-level governance, both below and beyond the state level, is steadily growing (Jogesh and Dubash, 2015; Jörgensen et al., 2015; Beermann et al., 2016). Discernible diversity across political systems and sectors in Asia notwithstanding, issues relevant to multilevel climate governance includes interplay between top-down national initiatives, which stem from supra-national, regional and sub-regional levels. In case of India, national climate governance has proliferated beyond the National Action Plan on Climate Change (NAPCC) to include State Action Plans on Climate Change (SAPCC) of over 28 states and union territories, demonstrating graphically the shared 'co-benefit' in terms of creating greater space for innovation and experimentation (Jörgensen et al., 2015).

In Japan's "Climate Change Adaptation Act", enacted by the Japanese Diet in June 2018, the national government shall formulate a National Action Plan (NAP) to promote adaptation in all sectors. Climate change adaptation act of Japan recommends prefectures and municipalities to designate "local climate change adaptation center (LCCAC)" as local climate change data collection and provision center, to provide more locally specific information and support for adaptation planning at the level of local municipalities. The Japanese government, in partnership with the private sector, has formulated a new comprehensive strategy, named Society 5.0, which aims at devising a number of technological innovative solutions (Mavrodieva and Shaw, 2020).

Significantly, the co-benefit concept for international city partnerships, comparative analysis of the challenges, capabilities and limitations of urban areas in Asia with regard to climate change adaptation governance remains under researched (Beermann et al., 2016).

In case of Vietnam, especially at district and commune levels, where the policy capacities in hierarchical governance systems to deal with climate change impacts are generally constrained, the value of clear legal institutions, provision of financing for implementing policies, and the training opportunities for governmental staff has been well demonstrated (Phuong et al., 2018b). A key finding is that any effort to support local actors (i.e. smallholder farmers) should ensure augmentation of policy capacity through necessary investments.

In case of China, a combination of market-based policies, emissions trading systems, growing number of environmental NGOs and international network appears to be serving as an important tool for climate governance, (Ramaswami et al., 2017; Wang et al., 2017b). Public private partnership (PPP) too is receiving increasing focus, especially with regard to climate related cost–effective and innovative infrastructure projects. In the absence of major investments in resilience, climate change may force up to 77 million people into poverty trap by 2030 (WorldBank, 2016). As seen in the case of Japan, most of the countries in Asia face the challenge of contractual allocation of risks associated with natural hazards and climate change between the public and private sectors and its long-term management in the face of uncertainty. Risk sharing, therefore could be addressed by clear definition and allocation (WorldBank, 2017). Given that in Asia, especially Singapore, China, Japan and Korea, water sector is a target of industrial and technology policy, PPPs could prove to be mutually beneficial. As a middle ground, key findings of a study on Indonesia (Yoseph-Paulus and Hindmarsh, 2016), underline the importance of building, sustaining and augmenting local capacity by addressing inadequacies with regard to resource endowment and capacity building, public awareness about climate change, government–community partnerships, vulnerability assessment, and providing inclusive decision making space to Indigenous Knowledge systems and communities.

In agriculture sector, farmers in Asia are adapting to climate change at the grass root level (Tripathi and Mishra, 2017). A recent, comprehensive and systematic review (Shaffril et al., 2018) shows how farmers in diverse sub-regions of Asia have adopted diverse adaptation strategies through management of crop, irrigation and water, farms, finances, physical infrastructure and social activities. Much more qualitative research on farmers' perceptions and decision-making about adaptation practices is needed in order to capture their location-specific priorities and diverse understanding of risks and threats. A study of Vietnamese smallholder farmer's perception of their current and future capacity to adapt to climate change (Phuong et al., 2018a) found considerable difference between farmers in crop production and livestock production in terms of their motives behind adopting particular planned adaptation options.

A study on farmers' awareness of and adaptation to climate change in the dry zones of Myanmar, critically dependent on agriculture, indicates how those in the frontline of the adverse effects of climate change are steadily abandoning the common sesame/groundnut cropping pattern, and trying to adapt to risks and uncertainties with the aid of conventional agricultural practices such as rainwater-collection, water-harvesting techniques, and resorting to the traditional weather forecasting techniques for weather prediction. Similarly, a case study of the Gandak Basin in Nepal shows that incorporation of local knowledge into agricultural practices and weather warning systems works best when coupled with multiple sources of information based on a method of triangulation. This also intersects with gender outcomes, where women frequently receive information from the men of their households, rather than directly from state institutional sources (Acharya and Prakash, 2019). Climate change adaptive governance is facilitated by improved cross-scalar and cross-sectoral cooperation, exchange of information and experiences and best practices (Smith et al., 2014; Watts et al., 2015; Gamble et al., 2016; Gilfillan et al., 2017).

An integrated approach informed by science, which examines multiple stressors along with Indigenous Knowledge, appears to be of immense value (Elum et al., 2017). A study on Pakistan concludes that poor agricultural communities are among the worst victims of climate change (Ali and Erenstein, 2017) and that farmers who are younger, better educated, belonging to joint families and possessing more landholdings are *likely* to adapt sooner and better. Correspondingly, this category achieved higher levels of income and food security. The climate-development nexus suggests that climate change adaptation practices at farm level can have significant development outcomes, besides reducing risk posed by changing weather patterns. Central to climate change adaptation (CCA) process is the growing recognition of the role that institutions play in both hierarchical setting and across different scales to influence implementation of CCA in diverse areas of governance across social and political domains. Cuevas (2018) highlights the usefulness of mainstreaming CCA into local land use planning in Albay, Philippines, by involving networks of interacting institutions and institutional arrangements for overcoming obstacles that are potentially counterproductive and conflictual.

As noted by AR5 (IPCC, 2014a), research on issues related to both climate change impacts on livestock production --demand for which is expected to double by 2050 in a world of 10 billion-- and policy choices with regard to adaptation, especially at the local scale, is still limited but in progress (Rojas-Downing et al., 2017). The promise of diversification of livestock animals (within species), crop diversification, and transition to mixed crop-livestock systems needs to be further explored. A study of livestock farmers in Pakistan shows that risk coping mechanisms such as purchasing livestock insurance and increasing land areas for fodder are far more rewarding policy options in comparison to selling livestock and migration. Relatedly, the association of migration with adaptation measure is context specific and involves a number of factors pertaining to the socio-economic circumstances of vulnerable agricultural groups in countries like India and Bangladesh (Ojha et al., 2014). In the 2010 United Nations Framework Convention on Climate Change's Cancun Adaptation Framework, migration was recognised as a form of adaptation that should be included in a country's long-term adaptation planning where appropriate (Paragraph 14f).

Also, agricultural climate adaptation policy targeting livestock farmers in rural areas is *very likely* to benefit from better education and awareness and increased access to extension services among livestock farmers on climate risk-coping choices and strategies (Rahut and Ali, 2018). In Myanmar, the lack of adequate agricultural extension strategies has had a negative impact on adaptation outcomes in what is labelled the central dry zone. Farmers' perceptions of climate change contribute to a comprehensive understanding of the context where they identify deforestation and related activities as the main culprits. Their adaptive methods include agricultural land preparation and crop rotation practices in addition to rainwater harvesting techniques (Swe et al., 2015). A study of vulnerable areas in Bangladesh (Alam et al., 2017), has shown that with policy support livestock rearing can prove to be a viable and substitute for crop production in areas prone to riverbank erosion. Carefully worked out partnerships between government organisations and NGOs can come to the rescue of poor farmers and their precarious households by providing information about best practices of local adaption strategies, including credit options with various institutions and creating an enabling environment for the promotion of agro-based industries. A study in community forestry in the Indian Himalayas (Gupta and Koontz, 2019) has shown how the synergies and successful partnerships could evolve between government and NGOs in local forest governance, with the former providing technical and financial support, and the latter directing the communities to those resources and in the making up for each other's limitations and thus enabling and augmenting community efforts in forest governance.

A study of Pakistan (Ali and Erenstein, 2017) shows that factors such as enhanced awareness about various climate risk coping strategies, better education and agricultural extension services, augmenting farm-household assets, lowering the cost of adaptation, improving access to services and alternative livelihoods, and providing support to poorer households appear to have paid rich dividends. Countries such as Bhutan and Sri Lanka have included provisions for 'climate-smart agriculture' in their NDCs (Amjath-Babu et al., 2019).

In the domain of forest adaptive governance, ever since the introduction of Reducing Emissions from Deforestation and forest Degradation plus (REDD+) at (COP 13) 2007 in Bali, the Indonesian experience suggests that some of the major challenges include curbing emissions, changes in cross-sectoral land-use as well as practice within forestry. and lack of effective, efficient and equitable implementation of diverse forest governance practices. The issue of how forest governance institutions are conceived and managed, both at national and sub-national levels, involving state, private sector and civil society, also needs serious attention (Agung et al., 2014).

In an example from Nepal, Clement (2018) shows that deliberative governance mechanisms can create the space for alternative framings of climate change to take a hold in ways that are cognisant of both the local and global contexts; this moves beyond a dependence on techno-managerialism in the construction of solutions, where local governance solutions can support institutional changes. The possibilities more incorporating deliberative methods into wider governance architecture are also expanded through an acknowledgment of the role of social learning; this is observable in the multi-stakeholder involvement that this approach fosters in regions of South Asia such as the Brahmaputra River Basin (Varma and Hazarika, 2018). Additionally, recent studies have reconfirmed the importance of linking Indigenous Knowledge with the scientific knowledge of climate change in diverse regions of the globe, including Asia and Africa (Hiwasaki et al., 2014; Etchart, 2017) (Taremwa et al., 2017) (Vadigi, 2017; Apraku et al., 2018; Inaotombi and Mahanta, 2018; Makondo and Thomas, 2018) for building farmers' resilience, enhancing climate change adaptation, ensuring cross cultural communication, promoting local skills, drawing upon Indigenous Peoples' intuitive thinking processes and geographical knowledge of remote areas.

A study of Sylhet Division in Bangladesh, deploying knowledge quality assessment' (KQA) tool found significant co-relation between a narrow technocratic problem framing, divorced from traditional knowledge strongly rooted in local socio-cultural histories and relatively low project success due to skewed risk-based calculation disconnected to the ground realities (Wani and Ariana, 2018) (Haque et al., 2017) while highlighting the vulnerability of the Bajo tribal communities, inhabiting the coastal areas of Indonesia, to climate change, share several examples of their Indigenous Knowledge and traditions of marine resource conservation, and show how this wisdom, a valuable asset for climate adaptation governance, has been passed from generation to generation through oral tradition.

10.5.1.3 Knowledge Gaps and Future directions

One of the major knowledge gaps in the domain of climate adaptation governance relates to implementation by various stakeholder at multiple scales and sharing of information and experiences in this regard. There is a need to assuage the perceptions of distrust in global information, through governance methods that engage multiple stakeholders in open and lucid channels of communication (Stott and Huq, 2014). This is observable in the structure of the New Urban Agenda which formed a part of the Sustainable Development Goal pertaining to cities and has been shaped by a bottom-up process marked by diverse participation including communities, experts and activists, rather than the top-down variant that is observable in the MDGs (Barnett and Parnell, 2016). This approach could also be evidenced in the Paris Agreement, which placed the onus of a successful global governance regime on the development of efficient systems of regional governance. However, these emerging systems of regional governance could equally pose a challenge to the global in way that can be witnessed through the development of such financial groups such as the BRICS and Asian Infrastructure Investment Bank (AIIB), which resulted from a perception of inadequate institutional transformation at the global level. From another perspective, a comprehensive approach would require simultaneous implementation of both Bottom-Up and Top-Down models of governance, retaining flexibility of scale.

Given the concerns surrounding food security, especially in the light of the principles of common but differentiated responsibility, under the Nationally Determined Contributions (NDCs) submitted by South Asian nations under the Paris agreement, emission reduction commitments are *less likely* to include agriculture sector. Prospects for enhancing both adaptive capacity and food security could be improved by strengthening resilience and profitability through the introduction of a basket of policy choices and actions including structural reforms, agriculture value chain interventions, and landscape-level efforts for climate resilience. Correspondingly, the substantial adaptation finance gap could be closed with the help of both private finance (autonomous adaptation) and international financial transfers (Amjath-Babu et al., 2019).

For nearly five decades, integrated coastal management (ICM), advocated by several international organisations (e.g., IMO, UNEP, WHO, FAO) and adopted by over 100 countries, has been acknowledged as a holistic coastal governance approach, aimed at achieving coastal sustainability and reducing the vulnerability of coastal communities in the face of multiple environmental impacts (*high confidence*). In view of threats posed to coastal ecological integrity by climate change induced tropical storm activity, accelerated sea level rise, and littoral erosion and socio-ecological impacts on the livelihood security of vulnerable coastal communities, the pressing need for approaches that innovatively combine coastal zone management and climate change adaptation measures, is widely acknowledged (Rosendo et al., 2018) yet under researched. A study focusing three coastal cities of Xiamen, Quanzhou and Dongying in China, a country with nearly 12% of national coastline already covered under the ICM governance framework, suggests that whereas ICM approach has been found to be effective in promoting the overall sustainability of China's coastal cities (Ye et al., 2015) using accurate and reliable data, as well as the developing unified standards could usefully reveal changing conditions and parameters related to ICM performance.

Steadily the regional scale of climate adaptive governance is acquiring salience in diverse sub-regions of Asia and more policy oriented empirical research is needed on how various regional forums, agencies and multilateral organisations could further contribute by way of in-house expertise and other resources, including financial. A study of climate adaptation in the health sector in South East Asia (Gilfillan, 2018) highlights the growing role of Asian Development Bank and the Asia-Pacific Regional Forum on Health and Environment, and shows that their mandates and goals could mutually benefit from the institutionalisation of coordination mechanism. An example from the Maldives shows that 2014 Tsunami, climate change and the risk of extreme weather events have led to the legitimisation of state-led population resettlement programmes; in China, this has occurred through the re-naming of previously existing resettlement initiative as climate adaption initiatives. However, the efficacy of resettlement as a CCA measure requires further scrutiny (Arnall, 2019). In India, the National Adaptation Fund on Climate Change (NAFCC) has been instituted in order to enable states to implement adaptation programmes. However, this does not address the question of mainstreaming CCA into designs for development (Prasad and Sud, 2019). This is closely related to the development of National Adaptation Programmes of Action (NAPAs) where the mainstreaming of adaptation within countries has been an important concern. Insights from developing countries indicate that there is still much ground to cover. The NAPA of the Maldives prioritises food security, coastal resources and public health, while Nepal has prioritised ecosystem management and public health, and food security, among other concerns (Saito, 2013). Importantly, Bangladesh's NAPA has shown that there is potential for 'reflexivity' in the integration of adaptation objectives with sectoral objectives (Vij et al., 2018). Conspicuous by its absence is the transboundary scale adaptation policies in South Asia (Vij et al., 2017).

A distinguishing feature of the case of Japanese apple growers is the co-existence of both top-down and bottom-up adaptation practices. The former pertains to farmers who rely on the support of the cooperative for agricultural support and follow institutional mechanisms. The latter pertains to non-co-op farmers who have been responsible for innovative practices of cultivation such as the shift to peaches and the sale in the market of apples without leaf-picking. Importantly, the non-co-op group also have access to sales channels that may not be accessible to the former owing to their direct interactions with customers, among other factors (Fujisawa and Kobayashi, 2011; Fujisawa et al., 2015) The significance of this combination of top-down and bottom-up approaches to agricultural adaptation practices may be further sharpened by formulating approaches for Asia and the Pacific region in ways that contribute to the fortification of food security objectives and the idea of co-benefits. This may be carried out by enhancing the ability of farmers to better manage cultivation practices in the context of climatic variability (FAO, 2018d).

There exist numerous barriers to the mainstreaming of climate change adaptation (CCA) measures across Asia. The integration of CCA into the dissemination of localised climatic information and its uptake and implementation through institutional policy arrangements remain areas of concern (Cuevas, 2018). Institutional incentives to agricultural production, for instance, are frequently compounded by the negative impacts these have on existing bases of natural resources. The disconnected operations of local governmental agencies coupled with inadequacies of cross-sectoral coordination further highlights the prevalent food-water-energy nexus (Rasul, 2016). One possible way of addressing these intersecting sources complexity is by locating emerging CCA measures in educational development. The introduction of CCA thinking into land use planning in the Philippines is an example of the successful role of enhancing public education and awareness through the dissemination of information by institutional channels. The linkages between the strength of local leadership and the inclusion of CCA in localised planning activities are also well illustrated by this case study (Cuevas, 2018).

As shown in the case of Pakistan, level of education shares a positive relationship with the implementation of adaptation measures (Ali and Erenstein, 2017). However, a closer examination of the educational imperatives that drive CCA in ways that improve the representational architecture of adaptation actions through a focus on gender is needed. Mainstreaming of gender into CCA would involve addressing a host of barriers to education and involvement that are often rooted in the differential structures of households, social norms and roles, and the domestic division of labour (Rao et al., 2019). A study from the Indian state of Bihar shows that gender plays a major role in determining intra-household decision making and also inhibits the ability of female-headed households to establish access to agricultural extension services (Mehar et al., 2016). Even within wider female farmer-operated federations such as the Bangladesh Kishani Sabha (BKS), the barriers to participation stem from social factors that include the limitation of female mobility through the gendered division of labour and a lack of recognition of female agency (Routledge, 2015). Gendered inequalities in educational attainment and outcomes viewed through the lens of social vulnerability thus intersect with environmental vulnerabilities in ways that affect the ability of women to participate in CCA, owing also to a lack of access to health and sanitation facilities. These factors have a direct impact on the ability of adaptation to be effective in the global South, and are especially important in the context of the commitments of CEDAW (UN Convention on the Elimination of All Forms of Discrimination Against Women) countries to the objective of gender equality (Roy, 2018).

[START BOX 10.6 HERE]

Box 10.6: Bangladesh Delta Plan 2100

"*The Bangladesh Delta Plan (BDP) 2100 is the plan moving Bangladesh forward for the next 100 years. We have formulated BDP 2100 in the way we want to build Bangladesh.*" (Commission, 2018).

Vision of BDP is revealed by this statement of Sheikh Hasina, the honourable Prime Minister of Bangladesh. Government approved BDP 2100 in 2018. Achievement of safe, climate resilient and prosperous delta is the aspiration of delta plan. Ensuring water and food security with economic growth, environmental sustainability, climate resilience, vulnerability reduction to natural hazards and minimising different challenges of delta through robust, adaptive and integrated strategies, and equitable water governance are the mission of this mega plan. Under this mission, three higher-level goals and six specific goals have been determined. Three higher-level goals include elimination of extreme poverty by 2030; achieve upper middle-income status by 2030 and being a prosperous country beyond 2041. Six specific goals of BDP 2100 are fully linked with SDG Goal 2, 6, 13 and 14 and partially linked with Goal 1, 5, 8, 9, 11 and 15. These specific goals comprise wide ranges of issues, including land and water resources, climate change, disaster, wetlands and ecosystems, river system and estuaries. Vision, mission and goals of BDP 2100 reveal that this mega plan is a holistic and integrated approach considering diversified themes and sectors for the whole country. The implementation of the BDP 2100 requires total spending of an amount of about 2.5% of GDP per annum. Series of strategies have been formulated for better implementation of the mega pan.

Water is the key and complicated resource of Bangladesh and therefore, BDP 2100 has kept water at the center of the plan. It aims to promote wise and integrated use of water and other resources through development of effective institutions and equitable governance for in-country and trans-boundary water resources management.

Along with water, for the first time in any development planning, BDP 2100 has taken the climate change issue as an exogenous variable in developing the macroeconomic framework of the plan. In a brief, it is said that the principle of BDP 2100 is "Living with Nature".

[END BOX 10.6 HERE]

10.5.2 Technology and Innovation

10.5.2.1 Point of Departure

Much like any other field, climate change adaptation is greatly facilitated by science, technology and continuous innovation. These ranges from the application of existing science, to the development of new scientific tools and methods, to the utilisation of Indigenous Knowledge and citizen sciences. Many of the pressing problems in Asia, including water scarcity, rapid urbanisation, loss of natural habitats, biodiversity, rising coastal and river basin hazards, and agricultural loss can be effectively minimised through the adoption of suitable science and technological methods. Despite the current challenges in the region, many significant advances in science and technology have been made, and the future prospects look bright. The following sections outline the present status and future prospects of science and technology in scaling up adaptation actions in four key sectors, namely disaster risk reduction, water and agriculture, urbanisation and forests and biodiversity.

10.5.2.2 Findings

10.5.2.2.1 Disaster Risk Reduction

Technological advances have enhanced the capabilities of Asian countries to monitor and prepare for climate-related hazards. Remote sensing technologies and GIS are widely used for disaster risk reduction (Kato et al., 2017), e.g., to assess and mitigate risks of an area to potential climate-related disasters (Wu et al., 2018b). The potential impacts of different types of hazards can be visualised using interactive maps (Lee, 2017), which helps local communities to understand risks and find appropriate evacuation areas (Cadiz, 2018). These provide situational overview and instant risk assessment (Yang et al., 2012b). As emerging technologies, artificial intelligence (AI) can identify conditioning factors of a landslide disaster (Hong et al., 2019b). Mobile virtual reality is used for disaster mitigation training, through a three-dimensional visualisation of a past disaster (Ghosh et al., 2018).

A community-based disaster risk reduction system provides risk investigation, training, and information analysis (Liu et al., 2016b). Sharing information enhances to establish such a system and contribute to disaster-prevention (Nakamura et al., 2017). One example is an online mapping tool, which has been developed by volunteers (Sakurai and Thapa, 2017). Social media enables population to reach real time information on a disaster (Ghosh et al., 2018), raises situation awareness (Yin et al., 2012), and empower communities towards appropriate emergency actions (Leong et al., 2015). Among various forms of social media, Twitter is widely used as social sensors to detect what is happening in a disaster event (Sakaki et al., 2013). Accuracy of information on Twitter has been proved in collecting local details about floods (Shi et al., 2019b), however it is noticed that Twitter generates rumors as well (Ogasahara et al., 2019). AI is expected to reduce human error when they operate a decision making system (Lin et al., 2018). Since technologies supporting disaster risk reduction completely depend on electricity, the loss of power supply and communication constrains the recovery work in disaster affected areas (Sakurai et al., 2014).

10.5.2.2.2 Urban sector

In the urban sector, a wide variety of sensor technologies are being used to monitor urban land-use and climate changes over time, and to better understand the potential impacts of future changes. These sensors range from large optical/thermal/radar satellite instruments with (near) global coverage (e.g., Landsat (US Geological Service), Sentinel (European Space Agency), ALOS (Japan Aerospace Exploration Agency), MethaneSAT to portable sensors embedded in mobile phones (e.g., phone cameras or temperature sensors) whose data are collected into centralised databases through crowdsourcing (Fenner et al., 2017; Meier et al., 2017). To combine and extract useful information from these heterogeneous sensor data – e.g., for conducting climate risk assessments (Perera and Emmanuel, 2018; Bechtel et al., 2019) and/or simulations of future land-use/climate changes in urban areas (Bateman et al., 2016), (Iizuka et al., 2017) (Liu et al., 2017c) – artificial intelligence technologies (e.g., machine-learning algorithms) are now being widely adopted (Johnson and Iizuka, 2016), (Joshi et al., 2016) (Mao et al., 2017). Thanks to advances in cloud computing technology, which allows for online processing of massive volumes of remote sensing data, high resolution (~30 meters) global urban area maps from the late 1990s to 2018 are now available from several different sources (Gong et al., 2020). Using these historical maps, researchers have been able to generate maps of future urban land-use changes at the global level to 2100 (Chen et al., 2020a), which can help to elucidate the potential impacts of this future urban expansion and identify adaptation needs. Technology also plays a major role in urban planning and design in the context of adaptation. To mitigate rising urban temperatures and reduce the impacts of climate-related hazards, many new "gray" infrastructure and "green" infrastructure technologies are being adopted in urban areas in Asia, e.g., cool (i.e. high solar reflectance) rooftops and pavements as well as green (i.e. vegetated) rooftops to mitigate high temperatures; and porous pavements to mitigate flooding (Akbari and Kolokotsa, 2016).

10.5.2.2.3 Water and agriculture

Majority of the Asian region is witnessing water stress in terms of both quantity and quality, due to poor management system and governance. This has dire consequences for national GDP as majority of the population belongs to agrarian community and their water dependent agriculture system. Despite a substantial investment and progress in research and development and capacity building in recent past, majority of the developing countries in Asian region are struggling to manage both water resources and agriculture sector heavily reliable on water resources, in lieu of rapid global changes. Considering the frequent extreme weather conditions, progress in management task become even more mammoth and hence need for advance science and technology viz. smart agriculture, robust early warning system using downscaled meteorological information, participatory approach, IWRM etc. for better climate change adaptation is critically important for these countries.

Having scientific knowledge relevant at local scale through placed knowledge is important to identify climate change risk and vulnerability. And once integrated with socio-economic attributes, it can be useful for natural resource management, agriculture etc. (Leith and Vanclay, 2017). Role of big data and data mining is undeniably very huge to get reliable climatic information and hence for designing appropriate adaptation measures for natural resource measurement. For example, use of big data in terms of early warning system and real time observation data provides more accurate information on hydro-meteorological extreme weather conditions or hazards like drought, flood, will help farmers and local government units to improve their perception and hence preparedness for better adaptation (Hou et al., 2017) (Ong and G.L.B.L., 2017). Using big data, different adaptation measures like new cultivar breeding, cropping region adjustment, irrigation pattern change, crop rotation and cropping practice optimisation are being designed in agriculture sector, which have greatly increased crop yield, leading to higher resource use efficiency as well as greatly increased soil organic carbon content with reduced greenhouse gas emissions. It results in win-win situation in terms of enhancing food security and mitigating climatic warming (Deng et al., 2017). However, usability and application of this technology are still not common especially in the data scarce regions. Integrated numerical simulations are efficient tools for estimating current status and predicting risk and efficiency of adaptive capabilities of different countermeasures for sustainable natural resource management like water (Kumar, 2019). Similarly, agent based model is commonly used to estimate risk of food borne diseases due to climate change, using tunable parameters such as hygiene level, microorganism's growth rate and number of consumers and hence has the potential to be a useful tool for optimising decision-making and urban planning strategies related to health and climate change (Gay Garcia et al., 2017). Integrated Assessment Model (IAM) under the Shared-Socioeconomic Pathway (SSP) framework is effectively used to estimate future energy development and possible mitigation strategies to reduce GHGs emission related to energy sector (Bauer et al., 2017). Sound understanding of different drivers, pressures and stress factors such as abnormal temperature, rainfall, insect pest/pathogen and their interaction pattern with genetic makeup of crops; is the key to produce high-yielding varieties of wheat with better nutritional quality and resistance to major diseases (Goel et al., 2017). Another critical point to address this water security is inclusive, polycentric and adaptive governance. Polycentric governance is a means that water management plans and policies should be framed and agreed by all relevant stakeholders. For adaptive governance, more emphasis will be on finding the best pathways to make robust water management plans amid rapid global changes. The benefit of such plans should reach the end users in terms of providing clean water, protection from hydrological hazards and maintaining the health of the ecosystem. In addition, there is urgent need for co-management, which includes the cycle of co-design, co-implementation and co-delivery throughout the whole water cycle. The best suitable example is using the Circulating and Ecological Sphere (CES) approach. CES is a concept that complements and supports regional resources by building broader networks, which is composed of natural connections (connections among forests; city and countryside; groundwater, rivers and the sea) and, economic connections (composed of human resources, funds, and others), thus complementing each other and generating synergy (Mavrodieva and Shaw, 2020). Another suitable example for managing water resources is Participatory Watershed Land-use Management (PWLM) approach. PWLM is another very innovative and successful approach for more robust water resource management explained by (Kumar et al., 2020). It helps to make land-use and climate change adaptation policies more effective at a local scale. This is an integrative method using both participating tactics and computer simulation modelling for water resource management at a regional scale.

10.5.2.2.4 Forests and Biodiversity

Technologies and its applications to identify habitat degradation, ecosystem functions and biodiversity conservation are increasing in Asia, with many countries looking up to new and improved means for forest and biodiversity monitoring and conservation. In particular, there has been an impressive use of temporal satellite data, particularly from the Landsat and the MODIS series for widespread monitoring of forests and ecological resources. These provided reliable information on forests and ecosystem services at country level, in difficult terrains, such as the mountains, cross-boundaries and otherwise inaccessible areas. For instance, Yin et al. (2017) estimated cross-boundary forest resources in Central Asia using remote sensing techniques, a region which traditionally suffered from lack of reliable forest data. In a separate study, Reddy et al. (2020) used long-term MODIS forest fire data from 2003–2017 to characterise fire frequency, density, and hotspots in South Asia. Archival of scientific data, particularly helped the provisioning of scientific research, backed by the state-of-the art modelling techniques, advance-computing methods and innovations in big data analysis. A number of studies simulated forest futures from local to continent scale under different socio-economic and climate scenarios. As for instance, at local scale, DasGupta et al. (2018) projected future extent of mangroves in the Sundarban delta under four local scenarios, while Estoque et al. (2019) modelled and developed spatial maps of regional forest futures in Southeast Asia using the five SSP scenarios. Science and technology also helped the monitoring of species diversity and abundance, pivotal for sustaining ecosystem and ecosystem based adaptation. Digital camera traps, radio-collaring methods have largely replaced old film cameras and labour-intensive methods of photo-screening to count target species (Pimm et al., 2015). This enhanced scientific capacities to monitor biodiversity and facilitate better conservation in difficult terrains, control poachers and maintain steady ecological balance. Umapathy et al. (2016), for example used VHF radio-collars and satellite-based tracking tools to monitor the movement of Bengal tigers in hostile island terrain. Photo recognition and other non-invasive techniques for individual identification have been rising in Asia. For example, a study by Gray et al. (2014) used fecal-DNA samples to estimate the population density of Asian elephant in Cambodia. The advancement of citizen science programs has greatly facilitated better monitoring of forest resources, including invasive floral and faunal species (Chandler et al., 2017; Johnson et al., 2020). In Asia, citizen science has been used effectively in India (Chandler et al., 2017), also in Malaysia for the monitoring the urban bird abundance (Puan et al., 2019).

10.5.2.3 Knowledge Gaps and Future Directions

With rapid advances of technologies, the use of appropriate technologies generates some degree of management problems. To resolve such problems, the enhancement of information science is essential to understanding design, implementation and adoption of digital tools under crisis (Xie et al., 2020). For example, social media research reveals a way of controlling malicious information (Tanaka et al., 2014) and its characteristics under Covid-19, showing a plain text message can be more powerful in the context of citizen engagement than media richness communications (Chen et al., 2020b). Information behaviour needs more investigation to understand how people survive and connect in the era of information overflow (Pan et al., 2020). Moreover, a new set of data e.g., travel history record and personal health data etc. becomes an important base of disaster risk reduction (Xie et al., 2020). Analysis of these personal data requires careful consideration, as it generates ethical issues (Sakurai and Chughtai, 2020). Indicators or measurements of technology enabled crisis response needs to be developed for further risk reduction (Wong et al., 2020). (Akbari and Kolokotsa, 2016). On the other hand, adopting infrastructure technologies requires investment, and due to the inherent uncertainties of climate projections, the future payoffs of these investments are also somewhat uncertain (Ginbo et al., 2020). In water and infrastructure sector for example, various options exist for conducting cost-benefit analysis considering future uncertainty, i.e. so-called robust approaches, which are able to identify adaptation projects/infrastructure that can achieve their intended purpose(s) across a wide range of climate scenarios (Dittrich et al., 2016). Despite a substantial investment and progress in research, development and capacity building in recent past, majority of the developing countries in Asian region are struggling to manage both water resources and agriculture sector. Considering the frequent extreme weather conditions, progress in management task has become even more mammoth and hence we need a holistic solution, which is currently missing in field implementation. These should be based on advance science and technology in association other attributes like social, economic, political dynamics, which play a pivotal role in sustainable management of water resources/agriculture, as a way forward.

10.5.3 Lifestyle Changes and Behavioural Factors

Point of departure: Understanding the motivations and processes underpinning decisions to adapt or not is key to enabling adaptation (Clayton et al., 2015; de Coninck et al., 2018; Taylor, 2019; van Valkengoed and Steg, 2019a; van Valkengoed and Steg, 2019b) (cross reference to Sec 17.2.2.1 in Chapter 17) because how and why certain people adapt is shaped by socio-cultural factors, ways of making sense of risks and uncertainty, and personal motivations to undertake action (Nguyen et al., 2016; Mortreux and Barnett, 2017; Singh et al., 2018b; van Valkengoed and Steg, 2019b). The IPCC's Assessment Report 5 was critiqued for silences on how perceptions shape climate action and the behavioural drivers of adaptation responses (Lorenzoni and Whitmarsh, 2014). Addressing this gap and assessing the growing literature from social sciences, notably psychology, behavioural economics, and risk perception studies, the IPCC Special Report on 1.5C (de Coninck et al., 2018) comprehensively assessed behavioural dimensions of climate change adaptation for the first time. However, compared to studies on mitigation behaviour, the literature on what motivates adaptation remains a gap (Lorenzoni and Whitmarsh, 2014; Clayton et al., 2015).

Findings: There are three key aspects of adaptation that psychology and behavioural science contribute to: understanding perceptions of climate risk, identifying the behavioural drivers of adaptation actions, and analysing the impacts of climate change on human well-being (Clayton et al., 2015). Overall, there is growing acknowledgement that individual adaptation is significantly shaped by perceptions of risk; perceived self-efficacy, i.e. beliefs about which options are effective and one's ability to implement specific adaptation interventions; socio-cultural norms and beliefs within which adaptation decisions are taken; past experiences of risk management; and the nature of the intervention itself (Grothmann and Patt, 2005; Werg et al., 2013; Clayton et al., 2015; Truelove et al., 2015; Pyhälä et al., 2016; Deng et al., 2017; Sullivan-Wiley and Short Gianotti, 2017; Taylor, 2019; van Valkengoed and Steg, 2019a). This is in addition to more commonly understood factors shaping adaptation behaviour such as technical know-how and cost and benefits associated with an option.

Across Asia, behavioural aspects of adaptation have been studied to a lesser extent: a global meta-analysis of 106 studies found most research focussed on North America and Europe with only 12% papers from Asia (van Valkengoed and Steg, 2019a). Within Asia, behavioural drivers of adaptation decision-making have been studied primarily in agriculture (in South, East, and SE Asia) and disaster risk management (from SE and East Asia) (Table 10.4) and tend to focus on technical adaptation interventions rather than how and why people adapt (Sun and Han, 2018).

Table 10.4: Table of sectors and sub-regions where behavioural aspects of adaptation have been assessed. NE= No Evidence

Sub-region	Sector	Adaptation interventions	Behavioural aspects affecting adaptation	Supporting references
West Asia	Agriculture	Soil and water conservation activities to mitigate drought impacts	Response efficacy and perceived severity shape water conservation	Iran (Keshavarz and Karami, 2016)
Central Asia	NE	NE	NE	NE
South Asia	Agriculture	Conservation agriculture, adjusting agricultural practices	Risk perceptions shape adoption of adaptation strategy (e.g. perceptions of decreasing rainfall motivate building water storage tanks)	Nepal (Piya et al., 2013; Halbrendt et al., 2014)
		Sustainable water management practices, adjusting agricultural practices	Risk perception is shaped by socio-cultural context, memories, experiences and expectations (of future change)	India (Singh et al., 2016)
		Alternate wetting and drying irrigation, alternative crop selection, using drought-resistant seeds	A combination of attitudes, self-efficacy, outcome efficacy, and community efficacy predict intent to adapt strongly	Sri Lanka (Truelove et al., 2015)
		Adjustment in farm management including growing short duration or drought-tolerant varieties, pest resistant varieties, changing planting distance, increasing weeding, soil conservation techniques, cultivation of direct seeded rice, switching to non-rice crops	Farmers' education, access to credit and extension services, experience with climate change impacts such as drought and flood, information on climate change issues, belief in climate change and the need to adapt all variously determine their decision-making	Nepal (Khanal et al., 2018)
	Disaster management	Flood and cyclone preparedness measures such as using durable building materials, raise plinth levels, storing food and water	Disaster management behaviour is intuitive: low evidence to suggest outcome-expectancy, self-efficacy, and preparedness intention follow linear patterns	India (Samaddar et al., 2014); Bangladesh (Dasgupta et al., 2014b)
		Use of emergency toolkits and evacuation plans	Risk perception and knowledge of adaptation options shape uptake and perceived benefits	Pakistan, Bangladesh (Alvi and Khayyam, 2020)
		Insurance to deal mitigate financial losses from floods, droughts	Frequency, severity of previous extreme events, socio-economic settings, ability to pay shape decisions to take crop insurance. Acceptability of flood insurance depends on perceived efficacy of the insurance (among other factors such as age of household head, landownership, off-farm income sources)	Pakistan (Arshad et al. 2016) (Abbas et al., 2015)

		Embankments/dikes for flood risk mitigation	Willingness to contribute manual labour to flood protection measures is positively influenced by the number of adult family members, livestock damage, compensation received and expected effectiveness of the intervention, but is negatively influenced by age and education of the household head, farm income and the distance of the farm from the river.	Pakistan (Abbas et al., 2019)
Southeast Asia	Agriculture	Changing agricultural practices, diversifying livelihoods	Values, personal and social beliefs of risk shape adaptation	Vietnam (Le Dang et al., 2014; Cullen and Anderson, 2016; Nguyen et al., 2016; Arunrat et al., 2017)
	Disaster management	Raising floor height to avoid flooding, retrofitting houses	Perceived probabilities and perceived consequences of flood shape preparedness	Vietnam (Reynaud et al., 2013; Ling et al., 2015)
		Flood insurance	Likelihood of purchasing flood insurance increased with higher physical exposure and subjective perceptions of vulnerability	Malaysia (Aliagha, 2013; Aliagha et al., 2014)
		Evacuation	Individual risk perceptions lead to learning, but only where previous disaster experiences are traumatic	Philippines, India (Walch, 2018)
		Disaster preparedness measures such as having kits, undertaking precautionary measures	Perceived self-efficacy was the most significant measure affecting reactive adaptation; education had the highest effect size on anticipatory adaptation.	Cambodia (Ung et al., 2015)
East Asia	Agriculture	Changing agricultural practices, diversifying incomes, adopting water saving technology, purchasing weather insurance	Perceived self-efficacy strongly predicts adaptive intent	China (Jianjun et al., 2015; Zhang et al., 2016a; Burnham and Ma, 2017; Feng et al., 2017)
	Disaster management	General	Higher education, being in environments where climate is discussed leads to stronger risk perceptions	Taiwan, Province of China (Sun and Han, 2018)
		Drought management through early warnings, prevention information	Policies can positively shape adaptation decision-making depending on how information is given, what support is provided	China (Wang et al., 2015).

In agriculture, studies demonstrate how perceptions of risk (e.g. climate variability) (Singh et al., 2016; Zheng and Dallimer, 2016; Burnham and Ma, 2017; Feng et al., 2017), socio-cultural norms and personal experiences (Masud, 2016; Nguyen et al., 2016; Singh et al., 2016), and perceived efficacy of adaptation interventions in having a positive/desirable impact (Halbrendt et al., 2014; Truelove et al., 2015; Feng et al., 2017) affect adaptation decisions. Policies on providing early warnings of drought or information on prevention techniques shape farmer decisions to undertake adaptation interventions (Wang et al., 2015).

In disaster risk management, risk appraisal (Samaddar et al., 2014; Rauf et al., 2017; Hung et al., 2018), previous experience and losses (Said et al., 2015; Hung et al., 2018; Walch, 2018)[11], perceived probabilities and consequences (Reynaud et al., 2013), perceived self-efficacy (Ung et al., 2015; Hung et al., 2018), and awareness (Hung et al., 2018; Wu et al., 2018a; Alvi and Khayyam, 2020) shape preparedness. Individual risk management is nested within public policies such as those on flood management which shape individual flood risk perception and protective behaviours (Reynaud et al., 2013) as well as personal factors such as religious beliefs (Alshehri et al., 2013). For example, communities often perceive disasters as 'acts of God' (Birkmann et al., 2019) or punishment for wrongdoings (Alshehri et al., 2013; Iqbal et al., 2018), which might constrain adaptive action. However, religious faith can also motivate people to prepare for extreme events, as Alshehri et al. (2013) show in Saudi Arabia demonstrating how "Islam urges that it is most important to prepare the people to escape from disaster" (p.1825).

Trust in public action as a mediator of risk management had conflicting evidence: some studies discussed trust being critical to effective preparedness (Kittipongvises and Mino, 2015; Walch, 2018) while others found that trust in public actions such as structural interventions to mitigate flood impacts can lower individual motivations to act since they feel protected (Hung et al., 2018).

Belief in climate variability and change significantly shapes adaptation decision-making (Le Dang et al., 2014; Singh et al., 2016; Khanal et al., 2018; Liu et al., 2018a) with those believing in climate change and associated impacts tending to engage in adaptation. Crucially, those who do not believe in climate change, can be influenced by social norms (Arunrat et al., 2017) thereby incentivising adaptation behaviour. While risk perception is a critical step in adaptation decision-making, higher risk perception does not necessarily signal better capacity to cope: in Taiwan, Province of China, Sun and Han (2018) highlight how perceptions of climate risk as a global problem tends reduce its urgency as an individual issue. Providing information on climate risks, impacts, and possible adaptation options enables adaptation behaviour (Piya et al., 2013; Zheng and Dallimer, 2016; Rauf et al., 2017) but information alone is not sufficient to motivate adaptive behaviour. Specifically, awareness building on concrete measures and outcomes such as amount of water saved or number of deaths averted rather than abstract notions of climate change motivate adaptation (Deng et al., 2017; Rauf et al., 2017).
Lifestyle changes: Changes in current lifestyles and consumption patterns are acknowledged as critical to climate action (de Coninck et al., 2018; IGES, 2019). With rapidly changing diets and increasing purchasing power, lifestyle changes in countries across Asia, especially those with large populations such as China and India will be critical to contributing to global climate solutions (IGES, 2019). Lifestyle shifts that can contribute towards adaptation include:

- Engaging in urban agriculture through rooftop gardening, community gardens in urban and peri-urban areas etc. (with implications for food associated footprints but also nutritional, livelihood, and wellbeing benefits) (Mohanty et al., 2012; Ackerman et al., 2014; Padgham and Dietrich, 2015)
- Shifts towards organic farming and creating demand for organically sourced food and other materials
- Shifts towards water-saving behaviour such as rainwater harvesting, water conservation, reducing water usage etc.

Knowledge gaps: Overall, understanding behavioural factors shaping adaptation implementation and uptake is important (*medium evidence, high agreement*). While there is a growing literature on behavioural drivers of adaptation at individual and household levels, gaps remain in understanding how socio-cognitive factors affect adaptation behaviour at higher scales (e.g. at local or sub-national government, in the private sector etc.)[12]. More empirical evidence is needed in sectors beyond agriculture and disaster risk management (e.g.

[11] Two exceptions to this were found. One is a survey in Saudi Arabia which tested public perceptions of disaster risk and found that direct experience with such disasters does not directly influence risk perception (Alshehri et al., 2013). Second, a study on flood experience and ensuing adaptation behaviour in Pakistan found that those with prior flood experience do not make significantly different choices than those who have no experience of flooding; what is more significant is repeated exposure to flooding events (Said et al., 2015)

[12] Some studies compare nationally representative surveys on climate perceptions and their impacts on climate action to demonstrate that higher risk perception leads to higher motivations to undertake climate action (Corner, Markowitz, and Pidgeon 2014; Smith and Mayer 2018). Others, however, highlight that higher risk perception can lead to a normalization

factors motivating urban adaptation) and better coverage across Asia's sub-regions. Importantly, there are no studies on behavioural aspects of adaptation from Central Asia.

10.5.4 Costs and Finance

10.5.4.1 Point of departure

Estimates of adaptation costs and financial needs have evolved significantly from the previous IPCC assessments. These developments are based on the improvements in the understanding on how the hazard interacts with the physical and socio-economic elements and how to capture these interactions in systematic modelling frameworks. The developments are also clearly reported especially in the area of addressing the underestimates in adaptation costs that the previous studies suffered from as the previous studies tend to rely on data from wealthy economies (Carleton et al., 2020);(Hochrainer-Stigler et al., 2014). The adaptation cost estimates also improved from the previous IPCC reports due to constant improvements in capturing the loss and damages of disaster events (Hochrainer-Stigler et al., 2014). The reliance of earlier studies on correlations to derive adaptation costs was addressed to some extent by addressing the endogeneity of disaster measures (Kousky, 2014), especially by relying upon the physical measures of disaster such as wind speed, though more work is needed in this area.

10.5.4.2 Findings

Climate change can cause significant impacts and as a result can impose considerable adaptation costs to countries and people. Despite the importance, the research on adaptation costs is limited in Asia, especially on the economy wide costs, while fragmented literature is available on sector level adaptation costs. Most of the available literature on adaptation costs at the regional level originate from the work carried out by the development finance institutions such as ADB.

Estimates suggest that climate change impacts could result in a loss of 2% of GDP of South Asian countries by 2050 and 9% by 2100 (Ahmed and Suphachalasai, 2014). These impacts will be felt in major vulnerable sectors, including agriculture, water, coastal, marine, health and energy, and will have significant impact on the economic growth and poverty reduction in the region. Countries could differ widely in terms of economic costs they face. In South Asia, the economic costs were projected to be 12.6% of GDP for the Maldives, which is the highest among the South Asian countries, and 6.6% for Sri Lanka, the least among the South Asian countries. The resultant adaptation costs for countries were projected to range from 0.36% (Copenhagen Cancun Scenario for 2050) to 1.32% (BAU scenario) of GDP in various scenarios during 2010-2050 (ibid) (*Medium agreement*, *limited evidence*).

Arto et al. (2019) have reported the adaptation costs of Mahanadi delta in India for agriculture, fisheries and infrastructure sectors (Arto et al., 2019). The cumulative adaptation costs for 2015-2016 were reported to be 276 million USD for agriculture and 0.163 million USD for fisheries. In comparison, the modelled cumulative agricultural GDP loss due to climate change impacts was reported to be 5% up to 2050, and 8% for infrastructure. Adaptation interventions such as embankments were found to provide an avoided losses (adaptation benefits) to the tune of 2.2% of the delta GDP by 2050. Similarly, input subsidies in seeds, fertilisers and biofertilisers were found to buffer the shocks in agriculture by 10%, and buffers the GDP per capita by 3% (ibid).

Markandya and González-Eguino (2019) have estimated the adaptation cots and residual adaptation costs accrued due to insufficient adaptation using integrated assessment models. Using the residual damages as a measure of loss and damage, the authors have estimated adaptation costs and residual costs under high damages-low discount rate and low damages-high discount rate scenarios. The estimates suggested adaptation costs of 182, 193 billion USD by 2050, 737, and 783 by 2100 for South Asia and East Asia respectively under high damages-low discount rate scenario. The residual costs for the same scenario were 289% and 76% for 2050 and 238% and 62% for 2100 for South Asia and East Asia respectively. Estimates

of risks, leading to lower climate action (Luís, Vauclair, and Lima 2018). In all of these papers, there is a recognition that the literature on perceptual drivers of climate action is US-centric and is negligible in Asia (Capstick et al. 2015).

for low damages-high discount rate were significantly lower adaptation costs and residual costs for both the sub-regions of Asia.

Climate change adaptation efforts can be characterised as fragmented, incoherent, and lacking a perspective (Ahmed et al., 2019a), and the picture on adaptation financing can be stated as similarly fragmented with very limited literature published in peer reviewed journals. Adaptation financing is crucial for supporting vulnerable countries enhance adaptation as it is evident that the enhanced adaptation finance support has positively affected the pace of adaptation in low-income countries (Ford et al., 2015). At the organisational level, adaptation financing provided multiple functions that include risk assessment functions, valuation functions, and risk disclosure functions (Linnenluecke et al., 2016).

Of the total global public adaptation finance of 28 billion USD, East Asia and Pacific attracted 46% of the total funding, while south Asian countries attracted only 9% of the total funding (UNEP, 2016). These differences reflect the capacity of countries to attract adaptation finance. Some of the important adaptation-targeted climate funds are Pilot Program for Climate Resilience, Green Climate Fund, and Least-Developed Countries Fund, and South Asian countries have significantly benefited from these dedicated climate funds. Due to disaster implications of climate change, there is a need to allocate adaptation finances for disaster risk reduction (DRR). Estimates suggest that East Asia and Pacific allocated 27% of the total adaptation funds to DRR while South Asia allocated 25% (Caravani, 2016). Low-income economies tend to allocate more adaptation funds to DRR (46%) while lower-middle income economies allocated 22%.

Least developed countries lack the capacity to adapt to climate change and the Least Developed Country Fund (LDCF) has been found to make significant contribution to adaptation in these countries (*High agreement, limited evidence*). Based on the interview-based field research in four least developed countries, Sovacool et al. (2017) opined that the LDCF projects are contributing to the adaptive capacity of these countries (Sovacool et al., 2017). They also found that these projects are taking a marginal approach to adaptation rather than radical or transformational one.

Kissinger et al. (2019) have estimated the climate financing needs in the land sector under Paris Agreement. The estimates suggested adaptation needs of 2.5 billion USD for Bangladesh, 40.5 million USD for Lao PDR, 31 million USD for Mongolia, for the forest sector alone (*Low agreement, limited evidence*).

Financing green growth and low-carbon development can provide resilience benefits (*High agreement, limited evidence*). Kameyama et al. (2016) have estimated the cost of low carbon investments that can provide resilience benefits in Asia and reported that such low-carbon development will cost in the range of USD125-149 billion annually. A combination of public, private, bilateral and multilateral funding sources, and carbon market offsets, were suggested to achieve this level of funding. In terms of the total resources available, a combination of public, private and bi-, and multilateral funding could help the region to raise as much as 222.3-412.5 billion USD annually, with a possibility to reach higher amounts depending on the future economic growth of countries in the region. Soil carbon sequestration in agricultural soils was found to be a win-win solution for both mitigation and adaptation as it can help improve soils while increasing farm yields and income of smallholders (Aryal et al., 2020a).

New adaptation financing sources have been emerging which could provide country-specific adaptation financing suiting local level adaptation needs in Asia. The newly established Asia Infrastructure Investment Bank (AIDB), and newly emerging developing country development finance institutions are known to provide an additional adaptation finance (Neufeldt et al., 2018). However, despite these emerging financial sources, the region will fall short of the adaptation target in the Paris Agreement (ibid).

10.5.4.3 Knowledge Gaps

Adaptation cost estimates can vary between various studies due to the differences in methodologies they adopt. Some studies have conducted cost assessments using a combination of stakeholder consultations and quantitative modelling of climate change impacts and adaptation (Ahmed and Suphachalasai, 2014), while others depended solely on the quantitative modelling. Studies also differ in the coverage of sectors too, they either focused on the multiple vulnerable sectors (Ahmed and Suphachalasai, 2014) or on a single sector (Hossain et al., 2019). Studies differed in their estimates depending on their ability to take into consideration the transition costs of sudden adaptation (Hossain et al., 2019), nature of social cost/damage functions employed (Arto et al., 2019), discount rates applied (Markandya and González-Eguino, 2019), and consideration for the effects of GHG mitigation on adaptation needs (Duan et al., 2019a). In addition, the assumptions made on the pace of adaptation in estimating adaptation costs can make a difference in adaptation cost estimates. Adaptation at a slow or normal pace could require more adaptation finance, as large amount of damage remain not eliminated, than when adaptation is implemented at a faster rate (Markandya and González-Eguino, 2019). Though there have been improvements in adaption cost estimates, there is a need to address the issue of endogeneity ((Kousky, 2014); (Samuel et al., 2019)). The vast majority of studies that rely on databases such as EM-DAT tend to suffer from such endogeneity problems due to their inability to control the causality between GDP and damages (Kousky, 2014). Costs attributable to non-economic loss and damages are the least reported and least quantified in the adaptation costs literature due to lack of sufficient, robust and accessible methodologies (Chiba et al., 2017); (Chiba et al., 2019); (Serdeczny, 2019)). This is a major limitation in assessing adaptation costs and financial needs and it can lead to gross underestimation of adaptation costs. A detailed description of issues related to non-economic loss and damages and its importance in strengthening adaptation is provided in Box 10.7 (Loss and damage across Asia: mapping the evidence and knowledge gaps), and Table 10.5.

[START BOX 10.7 HERE]

Box 10.7: Loss and Damage Across Asia: Mapping the Evidence and Knowledge Gaps

Losses and damages are climate impacts after implementing adaptation and mitigation actions, signifying the presence of residual risks (Kugler and Sariego, 2016; Mechler et al., 2019) (Chapter 1). These residual risks indicate that despite adaptation, there are soft and hard adaptation limits (Mechler et al., 2019). This box reviews the adaptation literature across 51 countries in Asia on L&D, and adaptation barriers and limits and identifies knowledge/regional gaps. The key messages are (1) climate-induced L&D is already occurring across Asia (*medium evidence, high agreement*), (2) these L&Ds are *very likely* to increase at higher warming levels (*medium evidence, high agreement*), and (3) measuring and attributing non-economic/intangible L&D remains a challenge (*low evidence, high agreement*).

Findings on losses and damages in Asia: Evidence on climate-related L&D highlights tangible or material losses and damages such as loss to life, property, infrastructure and livelihoods (*medium evidence, high agreement*); and intangible or non-material losses and damages such as increasing conflict and civil unrest, erosion of sociocultural practices, and decreased wellbeing (*low evidence, high agreement*). The main constraint in assessing past and future L&D is that this terminology is not used prominently or consistently in the disaster management and climate risk literature in Asia, which potentially leads to underreporting. In contrast, there is *robust evidence (high agreement*) on adaptation constraints, notably on governance, informational, and physical constraints to adapting but regional evidence is very uneven with gaps in Central, North and West Asia. Table 10.5 presents a summary of L&D but draws on national/sub-national studies.

Knowledge gaps

- Attribution studies linking anthropogenic climate change and L&D remain focused on rapid-onset extreme events and evidence on L&D from slow-onset events such as drought and water scarcity is low (Singh et al., 2021a) (Pereira et al., 2019).
- Regional evidence gaps in Central, North and West Asia. Further, *low evidence* of national-level projected loss and damages (Uchiyama et al., 2020; Singh et al., 2021a).
- Disproportionate emphasis on economic L&D while intangible, non-economic L&D are relatively less measured and reported (Chiba et al., 2017); (Bahinipati, 2020). Economic loss estimates are largely approximations and therefore suffer from various methodological, assumption, and data-related uncertainties.
- Insufficient literature differentiating L&D under future adaptation scenarios, which makes assessment of residual damages and future L&D difficult. L&D projections are constrained by limited understanding on how vulnerabilities will evolve with economic and demographic changes. Most projected L&D are based on the population and GDP projections. More future projections are based

on the RCP scenarios and least number of studies were conducted on the combination of RCP and shared socio-economic pathways.

- Mitigation will have L&D and adaptation co-benefits (Kugler and Sariego, 2016; Toussaint, 2020), especially at the lower temperature stabilisation 1.5ºC (Nishiura et al., 2020), but the literature is currently insufficient to assess these L&D co-benefits of mitigation efforts.
- Negligible regional evidence on limits to adaptation.

Way forward: Developing robust metrics and institutions for measuring and reporting L&D at national and regional scales, especially non-economic damages and L&D due to slow-onset events is critical. In addition to vulnerability assessments, assessing L&D and limits to adaptation can inform adaptation prioritisation and enhance adaptation effectiveness (e.g.(Craft and Fisher, 2016) (Leiter et al., 2019)). Lessons are available from biodiversity and ecosystem services monitoring frameworks that have well-developed metrics and processes (e.g., (Díaz et al., 2020)).

[END BOX 10.7 HERE]

Table 10.5: Tangible and intangible losses and damages across Asia. For definitions on losses and damages and limits, see Cross-Chapter Box LOSS in Chapter 1.

Magnitude of losses and damages	
(dark orange)	High (>50% sector/population affected relative to reported baseline)
(light orange)	Medium (25-50% sector/population affected)
(pale orange)	Low (<25% sector/population affected)
(grey)	Not assessed due to inadequate evidence

Evidence	
***	High (≥ 10 papers)
**	Medium (5-9 papers)
*	Low (≤ 4 papers)
NE	No evidence

Adaptation constraints	
E	Economic
S	Socio-cultural
H	Human capacity
G	Governance
F	Financial
I	Informational/Technology
P	Physical
B	Biological

Sub-region (no. of papers)	Key risks reported in L&D papers	Losses and damages					Adaptation constraints (bold ticks denote strong barrier)								Adaptation limits	
		Tangible				Intangible	E	S	H	G	F	I	P	B	Soft	Hard
		Past	RCP 2.5	RCP 4.5	RCP 8.5

10.5.5 Risk Insurance

10.5.4.1 Point of departure:

Risk insurance approaches and tools have significantly evolved during recent years. The emphasis has been mainly on mitigating the adverse selection and moral hazard that has been the limitations of traditional area-based crop insurance approaches (He et al., 2019). This has been achieved by shifting the indemnity calculations on to the specific weather parameters and developing a weather index (Greatrex et al., 2015); (Fischer, 2019). Technological applications in the development of insurance products have seen a significant progress, including that of the blockchain and smart contracts (Gatteschi et al., 2018). There are technological developments in loss estimation, which has been a major limitation in the traditional insurance approaches in the past that either delayed the indemnity payment or have misjudged the losses. Application of multi-model and multi-stage decision support systems has begun to make crop loss assessments for insurance more efficient (Aggarwal et al., 2020). Technological applications also include remote sensing (Di et al., 2017) and mobile phone app technologies (Meena et al., 2018) to provide accurate and quick damage assessments, and application of internet-based indemnity approvals have enabled quick payment of indemnities (OECD, 2017b).

10.5.4.2 Findings

As against financing post-disaster relief and reconstruction, which has been the norm of disaster management for decades in Asia, the evolution of ex-ante risk financing in the form of risk insurance has seen a steady rise globally and in Asia. The rise in popularity for risk financing in general and insurance in specific stem from the observation that governments have recognised the burden of mainly financing the post-disaster relief and reconstruction only (Juswanto and Nugroho, 2017; UNESCAP, 2018c; ADB, 2019), and from the realisation of cost savings and efficiency that risk financing for risk mitigation brings to the overall risk reduction (*High agreement*, *medium evidence*). As a result, a gamut of risk financing instruments have been introduced to finance disaster risk reduction and climate change adaptation initiatives in Asia among which risk insurance has gained prominence for it provides a low cost and easy option for individuals, provides an opportunity for the governments to effectively engage the private sector in implementation, and has ability to inculcate risk-aware decision making at various levels (Hazell and Hess, 2017; UNESCAP, 2018c) (*High agreement*, *medium evidence*).

Several Asian countries including India, The Philippines, China have a significant experience of offering agricultural insurance against typhoons, droughts and floods (Yang, 2018). For the most part, these insurance systems followed a traditional indemnity based insurance which faced several challenges in implementation including moral hazard and adverse selection, disagreements and delays in crop damage assessments that relied upon crop cutting experiments, often leading to delay in processing indemnity payments, costly insurance premiums, and poor insurance expansion (Patnaik and Swain, 2017; Ghosh et al., 2019) (*High agreement*, *robust evidence*). Other factors contributing to poor penetration of insurance include limited awareness on the importance of insurance, and poor access.

To tackle the problem of costly insurance premiums, governments have subsidised the premiums (Ghosh et al., 2019). Premium subsidies have been reported to undermine the ability to convey the real cost of risks by the insured (price distortion), and encouraged adverse selection and moral hazard (Nguyen and Jolly, 2019). On the contrary, subsidies have been suggested to address the issue of adverse selection associated with the insurance (Zhao et al., 2017c).

Despite the fact that the insurance programs are able to obtain high participation rates due to subsidised premiums, their impact on farmers' income seems to be insignificant especially under the conditions of low indemnities, low guarantee, and wide coverage (Zhao et al., 2016a). The subsidy burden of insurance on national governments is found to be significant with an estimated 6 billion dollars spent by China alone on insurance (Hazell et al., 2017). In addition, the insurance programs in the Asian countries are reporting higher producer claim ratios, and often governments have to spend more than the money being transferred to the insured through the insurance programs (ibid).

To address the issues associated with the traditional indemnity insurance, efforts have been made to develop weather index insurance in Asia that bases the payouts on the rainfall or temperature index rather than on the direct damage measurements. The parametric insurance products help avoid the delays in insurance payouts as they are based on modelled risks rather than actual damage measurements, and control the adverse selection and moral hazard though basis risks could be increased due to improper matching of payouts with the index (De Leeuw et al., 2014). Index insurance is known to promote public-private partnerships that in turn will enhance the efficiency of overall program delivery (Hazell and Hess, 2017). Several countries including India, Bangladesh, Thailand, Indonesia, Myanmar, and The Philippines either are currently piloting or are expanding the weather index insurance (Surminski and Oramas-Dorta, 2014; Tyagi and Joshi, 2019). Index insurance is constantly expanding with an estimated 194 million farmers already enrolled in China and India, which is much lower than the potential number of farmers it can reach (Hazell et al., 2017).

Few significant bottlenecks that are limiting the scaling up of weather index insurance include lack of reliable weather data, low density of weather stations leading to high basis risk, and limited data on damage and hazard for parametric modelling of the insurance (Shirsath et al., 2019). Several innovations are being tried and tested to overcome the limitations associated with the index insurance which include developing multiscale index insurance, application of remote sensing, smartphone based near-surface remote sensing, and building insurance based on vegetation indices instead of relying on weather data alone (Hufkens et al., 2019). Alternative indices such as using Normalised Difference Vegetation Index (NDVI) are being tested for their applications in designing index-based insurance in India (IFAD, 2017). Agro-meteorology-based statistical analysis and crop growth modelling have been suggested to calibrate and to rectify faulty weather indices (Shirsath et al., 2019; Zhu et al., 2019). Establishing automatic weather stations can improve the data accuracy while avoiding the delay in acquiring the weather data (Sinha and Tripathi, 2016). These technological applications have already started finding space within insurance programs designed by national governments in Asia. For example, the government of India has released new operational guidelines for the application of new technologies such as drones, remote sensing, and mobile phone apps in implementation of the national agricultural insurance which is the third largest insurance in the world (Department of Agriculture, 2019).

10.5.4.3 Knowledge Gaps

Despite these developments, several issues still seem to hinder the penetration of insurance in Asia. Issues such as lack of sufficient choices, lack of clear model, lack of legal support, limited or absence of proper monitoring and evaluation, and limited data for underwriters to properly evaluate claims have been suggested (Nguyen and Jolly, 2019). Low interest among the potential buyers due to unaffordable insurance premiums, lack of provision for partial loss claim settlement, high hassles in claim settlement process, and lack of timely settlement of claims are reported (Parappurathu et al., 2017). In addition, insurance has been reported to have expanded the coverage of cash crops at the expense of drought resistant subsistence crops with effects on natural capital and potential increase in farmer's vulnerability to market price fluctuations (Müller et al., 2017).

Regional catastrophic insurance pools have also received attention in Asia. With the formation of Southeast Asia Disaster Risk Insurance Facility (SEADRIF) (Haraguchi and Lall, 2019), the regional insurance pool has been introduced in the Southeast Asia region initially being piloted in Lao PDR and Myanmar and to be expanded to the rest of the ASEAN region. Regional catastrophic insurance provides vulnerable countries to buffer climatic shocks by diversifying the risks beyond country boundaries.

10.5.6 Social protection

10.5.6.1 Point of departure

Social protection (SP) encompasses of initiatives that involve transfer income or assets to the poor, protect the vulnerable against risks to their livelihood, and enhance the social status and rights of the marginalised (Béné et al., 2014; Kothari, 2014). Social protection offers a wide range of instruments (e.g., cash transfers, insurance products, pension schemes and employment guarantee schemes) that can be used to support households that are exposed to climate changes (Bank, 2015). It also presents an opportunity to develop inclusive comprehensive risk management strategies to address loss and damage from climate change as well as means to climate change adaptation (CCA) (Aleksandrova, 2019).

Social protection programmes assist individuals and families, especially the poor and vulnerable, cope with crises and shocks, finds jobs, improve productivity, invest in the health and education of their children, and protect the aging population (Bank, 2018b). Social protection that is well-designed and implemented in a more long-term approach can enhance human capital and productivity, reduce inequalities, build resilience, empowerment and end inter-generational cycle of poverty (*medium evidence, medium agreement*) as indicated from various experiences in the region such as cash transfer programmes in Indonesia (Kwon and Kim, 2015); Benazir Income Support Programme in Pakistan (Watson et al., 2017); Chars Livelihoods Programme in Bangladesh (Pritchard et al., 2015); Minsei-in designated volunteer social workers in Japan (Boeckmann, 2016). Key consideration in strengthening resilience through social protection programmes is to design with climate and disaster risk considerations in mind and implemented in close synergy with existing programs, such as on sustainable livelihoods, early warning systems, and financial inclusion (Bank, 2018a) (Coirolo et al., 2013).

10.5.6.2 Findings

The Asia region is already the most disaster prone in the world, with over 200,000 lives lost and almost a billion-people affected by storms and floods alone between 2005 and 2014, while a heat wave in North and Central Asia in 2010 killed 56,000 people (United Nations, 2015). Climate change is increasing the frequency and intensity of these sudden and slow-onset disasters, amongst them, hydrological changes in major river basins where 1.5 billion people live (such as the Indus, Ganges, Brahmaputra, Mekong, Yellow, Yangtze, Tarim, Amu and Syr Darya rivers) (Bank, 2017a). According to the latest estimates of the International Labour Organisation (ILO), 55% of the global population (around four billion people) remains without any SP benefits, whereas the SP coverage gap is the highest in Africa (82.2%) and Asia and the Pacific (61%) (ILO, 2017b).

Risks are generally amplified for people without social protection or essential infrastructure and services, and for people with limited access to land and quality housing, especially those in exposed areas and informal settlements without secure tenure (ESCAP, 2017). Stateless people are disproportionately affected by climate change and disasters as they tend to reside in hazard-prone areas and their statues as non-citizens often limits access to assistance (Connell, 2015). The three main types of social protection, namely (i) social safety nets (also known as social assistance), which include conditional and unconditional cash transfers, public work programs, subsidies, and food stamps; (ii) social insurance, which consists of contributory pensions and contributory health insurance; and (iii) labour market measures, which include instruments such as unemployment compensation (Bank, 2018b). The potential for an integrated adaptive social protection is not yet harnessed by policymakers in tackling the structural causes of vulnerability to climate change (Tenzing, 2019). Public works program, i.e. India's MGNREGA should take into account climate risk in planning and support development of community assets to increase collective resilience.

Aligning social protection with climate change interventions are attempts to develop more durable pathways out of poverty and climate vulnerability, examples from the Mahatma Gandhi National Rural Employment Guarantee Act in Andhra Pradesh (MGNREGA) depicts the attempt to align through mainstreaming approach has helped women and their households (Steinbach et al., 2016) (Adam, 2015). On another note, Catastrophe Insurance Framework, first model introduced in Shenzen, China, provides timely relief for citizens and operates as a safety net particularly for the poorest residents who do not have disposable income to cover the costs associated with bodily injuries arising from disasters (Telesetsky and He, 2016). The DOLE (Department of Labour and Employment) Integrated Livelihood and Emergency Employment Program (DILEEP) in Philippines, is part of the recovery efforts after Typhoon Haiyan, provide short-term wage employment and facilitates entrepreneurship for people affected by natural calamities and economic shocks (Bank, 2018b).

In each of these instances, governments are using social protection to protect populations suffering from climate change or adversely affected by structural, pro-climate economic reforms (Hallegatte et al., 2015) However, additional research is still needed and new tools developed to inform policy design and support the implementation of "green" social protection, as well as to measure the net welfare impacts of such policies

(Canonge, 2016). In order to enhance social protection programmes, one of the cross-cutting issues is to discuss the linkages between gender roles and responsibilities, food security, agricultural productivity and the mediating role that social protection programmes can have (Jones et al., 2017). Social protection has a potentially important role to play in contributing to food security and agricultural productivity in a gender-responsive way (Holmes and Jones, 2013). As such experience from Challenging the Frontiers of Poverty Reduction: Targeting the Ultra Poor (CFPR/TUP) programme in Bangladesh, promoted social innovation by creating social and economic values, fostering microenterprises, food security, fostering inclusive growth and whilst empowering ultra-poor women (Emran et al., 2014; Mahmuda et al., 2014). Although there is increasing evidence that social protection programmes are having positive impacts to reduce vulnerability in women's everyday lives (Jones et al., 2017). However, transformative impact of these programmes is rare due to limitation in recognising women's access to productive inputs and resources (Tanjeela and Rutherford, 2018; Cameron, 2019).

On the other hand, poor governance practices affect delivery of social protection programmes, and the ability of beneficiary households to reap benefits from such support (Sijapati, 2017). In Nepal, closer look at public expenditure, about 60% of social protection budget is used by social insurance programmes that predominantly consists of public sector pensions (Babken Babajanian, 2014; Koehler, 2014). Towards this end, more efforts needed to improve its existing programmes so that there is an equality of opportunities, along with secured human rights, citing example from Nepal's Child Grant is indicative of an incremental approach to social policy (Garde et al., 2017). Meanwhile, in Philippines despite the existence of flagship national interventions that cover a significant number of people in need and have clear and robust implementation rules, there are still many programs with overlapping mandates and target population, and several gaps in their monitoring systems (Bank, 2018b).

Thus, having an integrated social protection information system would allow policymakers to better monitor inputs, outputs and outcomes (e.g., who are beneficiaries, what are they receiving, at what frequency, what are the existing gaps) (OECD, 2017a; Samad and Shahid, 2018). Evidence-based from three countries' assessment (Mongolia, Nepal and Vietnam), the political and institutional arrangements (the software) is as important as the technical fixes (the hardware) in the success of using ICT for delivering social protection programs (ADB, 2016). By 2050, climate-induced migration will *likely* be a major policy aspect of the rural-urban nexus as slow onset impacts of climate change in Sub-Saharan Africa, South Asia, and Latin America will *likely* force over 143 million people to migrate within their national borders (Kumari Rigaud, 2018). This will have major implications for SP systems and therefore national SP strategies should be designed to anticipate and address climate-induced internal mobility (Schwan and Yu, 2017). For instance, it does not offer a solution for maintaining Indigenous culture often strongly affected or even disrupted by climate change (Olsson, 2014). Hence, an effective approach needs to combine different policy instruments to support protection, adaptation and migration (O'Brien et al., 2018).

Evidently, social protection has been typically financed through the combination of government tax revenues and Official Development Assistance (ODA) challenges of the increasing frequency and intensity of natural and economic crises, are putting strains on these traditional financial sources (Durán-Valverde, 2020).In this context, innovative financing schemes are seen as critical to achieve the sustainable financing of social protection (Asher, 2015; UNICEF, 2019) via social and solidarity economy, as seen in women's autonomous adaptation measures in precautionary savings and flood preparedness in Nepal (Banerjee et al., 2019), and self-help groups as development intermediaries (Anderson, 2019). Still, there are constraints of SP to reach those who are most vulnerable to climate change and other hazards due to their legal status, such as attention to forcibly displaced populations within the social protection field has been limited (Sabates-Wheeler, 2019).

10.5.6.3 Knowledge gaps

Government social protection can attenuate negative impacts in facing disasters, depending on difference in political systems and focus on socio-political measures (*medium evidence, medium agreement*) not only in restoring livelihoods but also easing mental burdens faced by rural households in developing countries (Kosec and Mo, 2017) (Dalton et al., 2016) (Liebenehm, 2018). However, limited government capacities and fiscal feasibility may impede the expansion and effective implementation of social protection as developing countries need further support to design, adjust and implement social protection schemes effectively

(Klonner, 2014; Schwan and Yu, 2017). Most countries have comprehensive strategies for both SP and CC, few have attempted to align them, as in practice, they remain in separate institutional homes, governed by their own intra-sector coordination groups and funding channels (Bank, 2018b) (Steinbach et al., 2016). Thus, significant knowledge gaps remain in terms of understanding the potential of SP to build long-term resilience to climate change (Ulrichs et al., 2019). Future efforts should be geared to develop climate-responsive social protection policies that consider a broad range of issues including urbanisation and migration, impact of green policies on the poor, access to essential health care and risks to socially marginalised groups (Aleksandrova, 2019). Along with strengthening links to climate information and early warning systems, finance for enabling social protection systems to address climate-related shocks and stresses dynamically needs to be scaled up (Ulrichs et al., 2019) (Kuriakose et al., 2013).

10.5.7 Education and Capacity Development

10.5.7.1 Point of departure

Countries with the least capacity are hit first and hardest by impacts, such as the Himalayan region and densely-populated deltas in Asia (De Souza et al., 2015); (Khan, 2017). Acknowledging the limitation in terms of capacity and coping mechanisms towards climate change, education, training and awareness-building is central to sustaining long-term capacity-building (Clemens et al., 2016). Education has lot more to offer and room for improvements in addressing climate change, particularly in the climate hotspots of the Asia region where mostly poor, disadvantaged and vulnerable communities to CC are residing (Mani et al., 2018). In particular, dissemination of climate change awareness and information need more explanation (Wi and Chang, 2018); (Steg et al., 2014),(Cho, 2020) international and national support through institutions and financing is critical for successful capacity-building (Hemachandra, 2019); capacity building must be designed for long-term and self-sustaining (Gustafson et al., 2018); national ownership by recipient countries and members of communities of capacity building efforts is key to ensuring their success (Mikulewicz, 2017); (Roberts and Pelling, 2016).

10.5.7.2 Findings

The need to develop tailored climate communication and education strategies for individual nations as public awareness and risk perceptions towards climate change vary greatly (Lee et al., 2015a) (*medium evidence, high agreement*). Improving and investing on basic education, climate literacy and place-based strategies of climate change are vital to enhance public engagement, societies adaptive capacity and support for climate action (Lutz et al., 2014c); (Hu and Chen, 2016). As stated in IPCC Special Report 1.5C sustainable development has the potential to significantly reduce systemic vulnerability, enhance adaptive capacity, and promote livelihood security for poor and disadvantaged populations (Roy et al., 2018). Hence, various concepts are introduced to foster awareness, understanding, knowledge, participation as well as commitment towards managing climate change in a sustainable manner, such as Education for Sustainable Development (ESD) aimed at integrating principles and practices of sustainable development in all aspects of education and learning to foster individuals who will contribute to the realisation of a more sustainable society (Kitamura, 2017).

Climate Change Education (CCE) is also now addressed in the context of Education for Sustainable Development (ESD) that allows for learners to understand the causes and consequences of climate change and their readiness to take actions (Mochizuki and Bryan, 2015). ESD and CCE are gaining broader attention, for instance in China (Han, 2015) and Korea (Sung, 2015), however development of policies and implementation of initiatives regarding ESD and CCE still face a handful of challenges, in which requires a strong political will and consensus of key stakeholders (Læssøe and Mochizuki, 2015). Effective communication on climate change education particularly for younger generation engagement is also essential as they are our future leaders as climate change is an inter-generational equity issue (Corner et al., 2015). Action for Climate Empowerment (ACE) of Article 6 UNFCCC, target youth as a major group for effective engagement in the formulation and implementation of decisions on climate change (UNFCCC, 2015). Increasing attention from countries in Asia, such as Thailand, India, to encourage innovative ways to provide adequately in educating and engaging youth in climate change issues (Dür and Keller, 2018); (Narksompong and Limjirakan, 2015).

Integrated approach of knowledge about climate change, embraces both the importance in bridging knowledge of climate science and respecting Local Knowledge and Indigenous Knowledge, should be at the heart of any effort to educate citizens to have a deeper understanding of the causes and consequence of climate change in a holistic manner (Aswani et al., 2018). Indigenous Peoples—comprising about six percent of the global population—play a crucial role in the fight against CC for two interlinked reasons, first, they have a particular physical and spiritual relationship with land, water and associated ecosystems and tend to be among the most vulnerable to CC (Magni, 2017). Second, they have a specialised ecological and traditional knowledge relevant to finding the best solutions to CC (Rautela and Karki, 2015). Indigenous knowledge systems and resource management practices are important tools for both mitigating and adapting to CC (Fernandez-Llamazares et al., 2015). Indigenous knowledge is increasingly recognised as a powerful tool for compiling evidence of CC over time (Ahmed et al., 2016a). Knowledge of Climate Change Adaptation (CCA) and Disaster Risk Reduction (DRR) provide a range of complementary approaches in building resilience and reducing the vulnerability of natural and human systems to the impacts of CC and environmental hazards (Mall et al., 2019). The adaptation dimension involves developing knowledge and utilising existing Local Knowledge and Indigenous Knowledge, skills and dispositions to better cope with already evident and looming climate impacts (Aghaei et al., 2018). It is also important to ensure inclusive efforts in DRR across different nations and communities as well as increasing skills and capacities of women towards DRR efforts (Hemachandra et al., 2018); (Reyes and Lu, 2016); (Drolet et al., 2015); (Alam and Rahman, 2014); (Islam et al., 2016b). More effective and efficient teaching and learning strategies as well as collaborative networks are needed to increase preparedness and DRR activities across various levels of community (Gampell et al., 2017); (Shiwaku et al., 2016); (Takahashi et al., 2015); (Oktari et al., 2015); (Tuladhar et al., 2015b).

As shown in Table 10.6, education and capacity-building aspects affecting adaptation by sub-regions examples.

Table 10.6: Education and capacity-building aspects affecting adaptation by sub-regions examples.

Sub-region		Adaptation interventions	Education and Capacity-building aspects affecting adaptation	Supporting references
North Asia	Human well-being	PEEX (Pan-Eurasian Experiment) originated from a bottom-up approach by the science communities aiming at resolving major uncertainties in Earth system science and global sustainability issues concerning the Arctic and boreal pan-Eurasian regions, as well as China	Educating next generation of multidisciplinary experts and scientists capable of finding tools in solving future environmental, socioeconomic and demographic development of the Arctic and boreal regions as well as China	Pan Eurasian regions, as well as China (Kulmala et al., 2015)
West Asia	Agriculture	Smallholders farmers' vulnerability assessment	Level of education high more human capacity, adaptive capacity, less vulnerability	Iran (Jamshidi et al., 2019)
Central Asia	Agriculture, Water Resources, and Energy	Carrying out the selection and cultivation of drought-tolerant salt tolerant crops, preservation of the upper watershed of the rivers, improve climate resilience of hydro-facilities	Focal point for the preparation and implementation of programs for CC at the regional level, increased capacity of professionals in targeted areas and networking between them, and strengthen institutional, technical and human resources to promote adaptation and research in fields of climate and hydrological investigations, geographical information systems (GIS), environmental impact assessment, and protection and re-cultivation of lands,	Kazakhstan, Tajikistan, and Kyrzigstan Mountain societies in Central Asia (Schmidt-Vogt et al., 2016) (Xenarios et al., 2019)

South Asia	Agriculture	Productivity, net crop income, improvement in livelihoods and food security	Farmers' education, easy access to farm advisory services, weather forecasting and marketing information affect adaptation decisions.	Pakistan (Abid et al., 2016)
		Passive adaptation in agricultural and farming practices implicitly to cope with climate change	Increasing knowledge on climate change crucial to take concrete steps dealing with perceived climatic changes	India (Tripathi and Mishra, 2017)
		Farmers' perceptions shape knowledge vice versa on climate change	Age, education, occupation, farming experience, knowledge about coping strategies, significantly related with farmers' perception about climate change.	India (Aslam Ansari, 2018)
	Disaster Risk Reduction	Local institutions preparedness and capacity managing disaster at local scale	Capacity-building, technical support and financial capacity as well as adopt proactive approach to achieve higher level of disaster preparedness.	Pakistan (Shah et al., 2019)
Southeast Asia	Agriculture	Farm cultural practices adopt to minimise production losses due to extreme weather	Small scale farmers' attendance in climate change training enhance adaptive capacity.	Vietnam (Trinh et al., 2018)
		Farmers' barriers to adopt adaptation measures lack of fund and timely information	Knowledge of crop variety, increase educational outreach and communicating CC related information likelihood employ adaptive strategies.	China (Zhai et al., 2018)
		In Lower Mekong Basin, farmers in rural, under-resourced communities are unaware of how climate change will affect them.	Scientific findings can be merged with local knowledge at a community level to help raise awareness; knowledge gaps on both can be filled for better understanding and adaptation planning.	Cambodia, Laos, Vietnam, Thailand (USAID, 2015); (Gustafson et al., 2018)
	Coastal areas	Households' vulnerability due to variation in socio-economic and livelihoods assets.	Increase resilience by establishing effective communication system, improve knowledge on climate.	Vietnam; Indonesia ((Huynh and Stringer, 2018); (Nanlohy et al., 2015)
	Disaster Risk Reduction	Capacity-building through learning lab on disaster risk management for sustainable development (DRM-SD).	Transfer learning initiative to provide approach guidelines and innovative mechanisms for DRM practitioners who will have the know-how and potential for leadership in DRM-SD.	Four ASEAN countries; Malaysia, Vietnam, Lao PDR, Cambodia (Ahmad Shabudin et al., 2017)
East Asia	Disaster Risk Reduction	Community participation and disaster education need to be conducted so that people can take actions in disaster management.	Educational resilience system tested and revised through experiences from past disasters. Also recognising gender perspectives into mainstream disaster management. 'School-based recovery concept' facilitates short-term recovery and the longer-term community building needs. It can also help communities in building new networks and solving chronic social problems.	Japan (Matsuura and Shaw, 2014; Saito, 2014; Shiwaku et al., 2016)
	Bridging Indigenous Knowledge and scientific knowledge	Effort to solve real-world problems should first engage with those local communities that are most affected, beginning	Paying attention to the Indigenous perception of a hazard and risk can increase the effectiveness of projects implemented by practitioners who might need to communicate risks in the future.	(Mistry and Berardi, 2016; Roder et al., 2016)

		from the perspective of Indigenous Knowledge and then seeking relevant scientific knowledge	Empowering younger generation to ensure continuity of Indigenous cultures and theirlinked ecosystems.	

Knowledge gaps: Capacity-building at national and local levels still need to address gaps in research and practice, such as impacts and results of different preparedness measures (Alcayna et al., 2016). Ad-hoc and localised documentations and monitoring of efforts to build adaptive capacities has rendered it difficult to assess success (Cinner et al., 2018). Recommendations for strengthened capacity building are sometimes made or understood in isolation from the underlying structural issues shaping vulnerability, or without adequately recognising the political relationships that mediate the ways in which particular technical interventions result in differentiated outcomes for different groups (Archer and Dodman, 2015). Thus, design and decision-based tools such as rapid assessment for community resilience to climate change as well as rapid approach to monitor the effectiveness of aid projects support community- based adaptation to climate change is analysed using multidimensional approach, procedural, distributional, rights and responsibilities (Nkoana et al., 2018); (Jacobson et al., 2019). As a model of communication and engagement, citizen science has the potential to promote individual and collective climate change action (Groulx et al., 2017). More than information provision is needed to mobilise public action on climate change (Kyburz-Graber, 2013). Citizen science links communication and engagement in a manner that hold important lessons on ways to promote collective responses to climate (Bonney et al., 2016); (Wals et al., 2014). The power of science-based citizen engagement lies in citizen group contribution in drawing upon their local knowledge to enrich the knowledge base required for management decisions (Sayer et al., 2015). Scientific evidence may be less attuned to the complexity of local realities in managing climate change, thus citizen science has the potential in bridging this gap and has many advantages for climate mitigation and adaptation practice and policy (Ford et al., 2016). While citizen science uses citizens as policy passive objects for research in conducting measurements for big data sets, citizen social science (CSS) is gaining its momentum where it repositions citizens as central co-learners that can widen the climate science evidence-base to a more holistic understanding for the benefit of all (Kythreotis et al., 2019).

10.6 Climate Resilient Development Pathways

10.6.1 Climate-resilient Development Pathways in Asia

Climate-resilient development pathways (CRDPs) are 'trajectories that strengthen sustainable development and efforts to eradicate poverty and reduce inequalities while promoting fair and cross-scalar adaptation to and resilience in a changing climate' (Roy et al., 2018). Moving beyond a business-as-usual scenario, CRDPs involve not only adaptation and mitigation choices but also sustainable development implications and societal transformation (Roy et al., 2018). This basic understanding of CRDPs explicitly reflects that climate action (mitigation and adaptation) and sustainable development are fundamentally integrated and interdependent.

There is *high confidence* that currently implemented climate action in Asia (such as climate smart agriculture, ecosystem-based disaster risk reduction, investing in urban blue-green infrastructure) can meet adaptation, mitigation, and sustainable development goals simultaneously, presenting opportunities for climate-resilient development (CRD). However, there also exist significant barriers to CRD such as fragmented, reactive governance; inadequate evidence on which actions to prioritise and how to sequence them; and finance deficits. Some Asia countries and regions offer solutions to overcome these barriers: Through use of advanced technologies (in-situ observation and remote sensing, a variety of new sensor technologies, citizen science, artificial intelligence, and machine learning tools); regional partnerships and learning; improved forecasting capabilities; and better risk awareness (*high confidence*).

Asian countries are repeatedly identified as the most vulnerable to climatic risks with key sectors such as agriculture, cities and infrastructure, and terrestrial ecosystems expected to see high exposure to multiple hazards (Section 10.3). Owing to rapid development and large populations, Asian countries have large and growing GHG emissions: in 2018, five of the top 10 emitters in the world were Asian : China (1), India (3), Japan (5) Republic of Korea (8), and Indonesia (10) (Friedlingstein et al., 2019) although it is critical to note that per capita emissions and cumulative emissions are relatively lower than developed economies (Raupach et al., 2014). However, in the 2020 Sustainability Index and Dashboard, only two Asian countries made it to the top 30 countries in the world: Japan (17) and Republic of Korea (20) (Sachs et al., 2020). Finally, Asia has varied capacities to adapt with high heterogeneity in adaptation progress across the region.

Given this context of high risks, growing emissions, and varied adaptive capacities in Asia, CRDPs can enable (1) reducing existing vulnerability and inequality, (2) sustainable development and meeting the SDGs, and (3) managing multiple and often concurrent risks, including climate change and disaster risks Potentially, combinations of adaptation and mitigation options will be required to lead to climate-resilient development (see Fig on CRDPs in Ch 18) and some of these are outlined in Table 10.7. For example, climate-smart agriculture strengthens food security (SDG 2, Zero Hunger) (Aggarwal et al., 2019); urban disaster management such as Jakarta Disaster Risk Reduction Education Initiative contributes to SDG 11 (Sustainable Cities) (Ajibade et al., 2019).

Table 10.7: Adaptation options that can have mitigation and SDG synergies and trade-offs, providing opportunities for triple wins necessary for CRDPs.

Adaptation option	**Mitigation impacts (H/M/L/NA)[a]**	**Implications on SDGs**		**References**
		Positive	**Negative**	
Wetland protection, restoration	*Medium synergy* Carbon sequestration through mangroves	SDGs 8, 14, 15		(Griscom et al., 2020) in SE Asia
Solar drip irrigation	*High synergy* Shift to cleaner energy	SDGs 2, 7, 12	SDG 10	(Alam et al., 2020) in South Asia
Climate-smart agriculture	*High synergy [b]* No till practices and improved residue management can reduce soil carbon emissions	SDGs 2, 12		(Aggarwal et al., 2019), (Aryal et al., 2020b), (Aryal et al., 2020a), and (Tankha et al., 2020) in South Asia; (Chandra and McNamara, 2018) in SE Asia
Integrated smart water grids	*High synergy* Reduced energy needs for supplying water	SDGs 6, 9, 11, 13		(Kim, 2017) in Asia
Disaster risk management (including early warning systems)[c]	Not applicable	SDGs 9, 11	SDGs 5, 10	(Ajibade et al., 2019), (Herbeck and Flitner, 2019), (Aryal et al., 2020b) and (Mishra, 2020) in South and SE Asia; (Iturrizaga, 2019) in Asia; (Sovacool et al., 2012) in Bhutan; Grefalda et al. (2020) in Philippines
Carefully planned resettlement and migration (including decongestion of urban areas)	Inadequate evidence to make an assessment	SDGs 8, 10, 11	SDGs 6, 10, 11	(Arnall, 2019) in Asia; (Maharjan et al., 2020) in South Asia; (Estoque et al., 2020) in the Philippines; Banerjee et al. (2019) in Nepal
Aquifer storage and recovery	*Low synergy*	SDGs 6, 12		(Lopez et al., 2014) in Saudi Arabia; (Hoque et al., 2016) in South and SE Asia
Nature-based solutions in urban areas: green infrastructure (including urban green space, blue-green infrastructure)	*High synergy* Blue-green infrastructure act as carbon sinks	SDGs 3, 9, 11		(Mabon et al., 2019) in Japan; (Estoque et al., 2020) in the Philippines; (Byrne et al., 2015) and (Zhang et al., 2020a) in China; (Mabon and Shih, 2018) in Taiwan, Province of China; (Liao, 2019) and (Radhakrishnan et al., 2019) in Singapore
Coastal green infrastructure	*High synergy*	SDGs 9, 11, 13, 14, 15		(Sovacool et al., 2012), (Chow, 2018) and (Zinia and McShane, 2018) in Bangladesh; (Koh and

				Teh, 2019) and (Herbeck and Flitner, 2019) in SE Asia; (Giffin et al., 2020) in Asia

Table Notes:
[a] Expert judgement
[b] Climate change adaptation options in the agricultural sector include soil management, crop diversification, cropping system optimisation, and management, water management, sustainable land management, crop pest and disease management, and direct seeding of rice (Aryal et al., 2020b). Other specific agricultural practices that have adaptation and mitigation synergies include between tillage and residue management, alternate wetting and drying, site-specific nutrient management, crop diversification to less water-intensive crops such as maize, and improved livestock management (Aryal et al., 2020a).
[c] Risk management strategies in agriculture include crop insurance, index insurance, social networking and community-based adaptation, collective international action, and integrated agro-meteorological advisory services (Aryal et al., 2020b).

The following sub-sections examine CRDPs through three approaches that are particularly important in Asia and have a large body of evidence to assess implications for adaptation, mitigation, and sustainable development. The three illustrative approaches are: (1) Disaster risk management and adaptation synergies; (2) Food Water Energy Nexus; (3) Poverty alleviation and meeting equity goals.

10.6.2 Disaster Risk Reduction and Climate Change Adaptation Linkages

10.6.2.1 Point of Departure

There is growing evidence on the interconnectedness of extreme weather, climate change and disaster impacts (Asia, 2017; Reyer, 2017). In the Asian region, climate-related disasters have become more recurrent and destructive in terms of both economic and social impacts (Bhatt et al., 2015); (Aich et al., 2017); (Vij et al., 2017). Projections of increasing frequency, intensity, and severity of climate-related disasters call for better integration of climate change adaptation and disaster risk reduction (Sapountzaki, 2018) in policy development to address risks efficiently (Rahman et al., 2018) and to promote sustainable development pathways for reduced vulnerability and increased resilience(Seidler et al., 2018). Connecting climate change adaptation and disaster risk reduction efforts in both policy and practice continue to be a challenge, however, because the convergence of national policy and planning processes on CCA and DRR within Asia is in its early stages (Cousins, 2014) and structural barriers persist (Mall et al., 2019). CCA and DRR have developed as separate policy domains because of the different temporal and spatial scales considered, the diversity of actors involved, the policies and institutional frameworks adopted, and differences in tools and methodological approaches used. This has resulted to the CCA and DRR communities, and the knowledge and research they produce to support planning and decision making not always being well connected (Street et al., 2019).

10.6.2.2 Findings

Climate risk management in Asia is approached by focusing on hazards that are associated with extremes, i.e., extreme weather events with increased frequency and severity, and climate-and weather-related events. For example, farming has been affected by climatic variability and change in a wide variety of ways that include an increase in drought periods and intensity, a shortage of irrigation water availability, an increase in flooding and landslides, pest infestation of crops, a rising number of crop diseases, the introduction of invasive species and crop weeds, land degradation and an overall reduction in crop yields (Khanal et al., 2019). Estimation of the number of daily patients of heat-related illness based on the weather data and newly introduced metrics shows that the effects of age, successive days, and heat adaptation are key variables (Kodera et al., 2019).

Because most developing countries in Asia are highly vulnerable to the impacts of climate change due to a number of factors, many studies have focused on understanding vulnerability, for instance, gendered vulnerability at micro scale, which limits capacity to respond to both climatic and socioeconomic stressors (Ferdous and Mallick, 2019); vulnerability of urban poor communities due to the interaction of environmental and social factors (e.g., low incomes, gender, migrant status) and heightens the impacts of climate change on the poor (Porio, 2014); socio-ecological vulnerability where a degraded environment influences hazard patterns and vulnerability of people (Depietri, 2020); and livelihood vulnerability due to perceived climate risks and adaptation constraints (Fahad and Wang, 2018); (Hossain et al., 2020).

Risk assessments have been undertaken for different hazards such as floods (Al Saud, 2015; Al-Amin et al., 2019; Jha and Gundimeda, 2019; Mahmood et al., 2019; Zhang et al., 2019e); drought (Guo et al., 2019; Mainali et al., 2019); rainfall-induced landslide (Li et al., 2019b), sea level rise (Imaduddina and Subagyo, 2014; Suroso and Firman, 2018) and heat stress (Onosuka et al., 2019), among others, as well as environmental assessment, for example, in coastal zones (Islam and Zhang, 2019). Different types of strategies for climate risk management have also been studied including in-situ adaptation through ecosystem-based and community-based adaptation (Jamero et al., 2017); managed retreat or relocation (Buchori et al., 2018; Doberstein et al., 2020); planned sheltering in flood zones (Wu et al., 2019c); sustainable livelihoods that consider long term CCA measures of farmers and fishermen (Nizami et al., 2019; Shaffril et al., 2019); coastal afforestation through mangrove plantation (Rahman et al., 2018); management of ecosystem services to mitigate the effects of droughts (Tran and Brown, 2019); pre-investments, including holistic assessment of the basin (Inaoka et al., 2019); institutionalisation, where entry points are identified in efforts to build resilience (Lassa, 2019) and adaptive governance (Walch, 2019); and linking science and local knowledge (Mehta et al., 2019; van Gevelt et al., 2019).

The sectors that CCA and DRR have been linked are varied: (Filho et al., 2019) assessed adaptive capacity and resilience to climate change based on urban poverty, infrastructure and community facilities; (Mabon et al., 2019) looked at adaptation via the built environment, green roofs, and citizen and private sector involvement in smaller-scale greening actions; (Lama and Becker, 2019) focused on adaptation to reduce risk in conflicts; (Banwell et al., 2018) studied the link between health, CCA and DRR; and (Izumi et al., 2019) surveyed science, technology and innovation for DRR, {Banwell, 2018, Towards Improved Linkage of Disaster Risk Reduction and Climate Change Adaptation in Health: A Review} to name a few. Vulnerable groups have been given much attention such as farmers (Afroz, 2017; Gupta et al., 2019; Jawid and Khadjavi, 2019; Khanal et al., 2019; Shi et al., 2019a), women (Goodrich et al., 2019; Udas et al., 2019); (Hossain et al., 2019); and children, elderly and refugees (Asia, 2017). Finally, issues identified include water resources management (Bhatta et al., 2019; Sen et al., 2019; Zhang et al., 2019a); food security (Aleksandrova et al., 2016; Le, 2016); disaster governance (Blanco, 2015); climate boundary shifting wherein impacts of climate change are significant for crop production, soil management, and DRR (Talchabhadel and Karki, 2019); and institutional dimensions of CCA (Cuevas, 2018); (Islam et al., 2020).

Case studies on climate risk management and integrated CCA and DRR actions highlight some key lessons including an integrated and transformative approach to CCA, which focuses on long term changes in addressing climate impacts (Filho et al., 2019); adoption of an adaptive flood risk management framework incorporating both risk observation and public perceptions (Al-Amin et al., 2019); holistic approach and non-structural and technological measures in flood control management (Chan, 2014); monitoring of changes in urban surface water in relation to changes in seasons, land covers, anthropogenic activities, and topographical characteristics for managing watersheds and urban planning (Faridatul et al., 2019); removing 'gender blindness' in agrobiodiversity conservation and adaptation policies (Ravera et al., 2019); understanding uncertainties in CCA and DRR at the local level (van der Keur et al., 2016; Djalante and Lassa, 2019); promoting the use of Local Knowledge and Indigenous Knowledge alongside scientific knowledge (Hiwasaki et al., 2014); and increasing information, education and communication activities, and capacity development on DRR at the local level (Tuladhar et al., 2015a).

Several studies also identify enabling conditions to effectively implement CCA and DRR actions. In the Arab region in Asia (ARA), the following are critical: capacity building to develop knowledge and awareness, mainstreaming CCA and DRR in the national strategies and policies (e.g., water and environmental strategies), empowering the role of CCA and DRR actors notably women and rural societies, adopting lessons learned from regions with similar physical characteristics to ARA, establishing forecasting and prediction platforms that is supported by advanced monitoring technologies (e.g., remote sensing), and encouraging universities and research centers to develop studies on CCA and DRR. In Southeast Asia, laws and policies, institutional and financial arrangements, risk assessment, capacity building, and planning and implementation are entry points in integrating CCA and DRR (Lassa and Sembiring, 2017; Agency, 2018). According to (Cutter et al., 2015), holistic solutions and integrated approaches, rigorous risk research that shows coherent science-based assessment and knowledge transfer from research to practice, and aligned targets on disaster risk management, climate change and sustainable development targets are critical. Social capital and social protection measures could promote pro-poor and gender responsive adaptation and socially inclusive policy (Dilshad et al., 2019; Yari et al., 2019). Community-based approaches could allow local perceptions of climate change and experience of place to be included in planning (Dujardin et al., 2018; Dwirahmadi et al., 2019; Widiati and Irianto, 2019) and multi-stakeholder participation could engage various actors like the private sector in CCA and DRR. Further, multi-level climate governance could benefit from vertical and horizontal interactions at different levels and layers in the city (Zen et al., 2019). To mainstream and secure funding commitment, CCA and DRR could be integrated into national development plans and sectoral long-term plans (Ishiwatari and Surjan, 2020; Rahayu et al., 2020; Rani et al., 2020b).

10.6.2.3 Knowledge Gaps

Adaptation follows knowledge on risks, and literature exists that systematically identifies and characterises exposure and vulnerability, but gaps still exist. Decision making under uncertainty is challenged by the lack of data for adapting to current and uncertain future climate, the different perceptions of risk, and the potential solutions across different cultures and languages (van der Keur et al., 2016). Lack of downscaled climatic data, diverse institutional structures, and missing links in policies, are among the challenges in South Asia (Mall et al., 2019). In agriculture, there are gaps in the use of advanced farming techniques such as drought-resistant crops, and information on climate change to support farming households in making adaptation decisions (Akhtar et al., 2019; Khanal et al., 2019; Ullah et al., 2019). Better understanding of effective water management is crucial due to conflicts for shared water in ARA (Shaban and Hamze, 2017; UNDP, 2018). For delta regions, gaps identified are methodologies and approaches appropriate for understanding social vulnerability at various scales, pathways required for adaptation policy and response in the deltas that transcend development, and the lessons from implemented policy and how practice can build on these lessons in the deltas, among others (Lwasa, 2015). Approaches in tackling the challenges of climate change and disasters in the cities of developing countries could be better understood, and shared between cities so they can learn from one another (Filho et al., 2019).

10.6.3 Food Water Energy Nexus

Point of Departure: Food, energy, water, and land are vital elements for sustainable development as well as enhancing resilience to both climatic and non-climatic shocks. All these resources are highly vulnerable to climate change (10.3.1; 10.3.4; 10.3.4). Poor people are most affected due to changes in resources availability and accessibility. Food, water, and energy security are interconnected (Bizikova et al., 2013; Ringler et al., 2013; Rasul, 2014; Chang et al., 2016; Ringler et al., 2016). Although adapting to the climate change is one of the core component of global, regional, national and sub-national agenda, the focus of adaptation action has remained sectoral. Undermining the interlinkages of food energy and water security may increase trade-offs between sectors or places, which may lead to maladaptation (Barnett and O'Neill, 2010; Howells et al., 2013; Lele et al., 2013). Therefore, focusing on the nature of trade-offs and synergies across food water and energy nexus for integrated management of resources is a potential strategy for adaption to both climatic and non-climatic challenges (Bhaduri et al., 2015; Zaman et al., 2017). Due to its importance to the Paris Agreement and Sustainable Development Goals (SDGs), food water energy nexus approach got increasing attentions to capture synergies and minimise trade-offs in this interconnected system, which is also critical for enhancing adaptation together (Bazilian et al., 2011; Lawford et al., 2013; UNESCAP, 2013; FAO, 2014; Rasul and Sharma, 2014; Taniguchi et al., 2017a; Sukhwani et al., 2019; Sukhwani et al., 2020).

Findings: The FEW nexus can be evaluated in the two-way interactions between water-food, water-energy and food energy (Taniguchi et al., 2017a). The water energy nexus includes water for energy and energy for water (Rothausen and Conway, 2011; Hussey and Pittock, 2012; Byers et al., 2014), water food nexus, which includes water for food and impact of food production on water (Hoekstra and Mekonnen, 2012) and energy consumption for food production and food crops for biofuel production (Tilman et al., 2009). Food water energy land nexus has diversified implications at the sub-regional level in Asia. The increase in water supply-gap raises questions about sustainability of main mode of electricity generation in South Asia-thermal power generation and hydropower generation- are both threatened by water shortage in South Asia (Luo, 2018b; Mitra et al., 2021). Furthermore, policy mismatch driven anthropogenic cause lead unsustainable water use for food production in India. For example, subsidised electricity supply for watering agriculture plays key role in losing groundwater's buffer capacity against the various changes including climate variabilities (Badiani et al., 2012; Mitra, 2017). In the Mekong River basin of Southeast Asia, massive and rapid export oriented hydropower development will have direct implication on regional food security and livelihoods through major negative effect on the aquatic ecosystem (Baran and Myschowoda, 2009; Dugan et al., 2010; Arias et al., 2014). Similarly, in Central Asia, shifting of water storage for irrigation to power development has increased risks on reliable quality and quality of water (Granit et al., 2012). Deforestation lead agro-environmental changes led to decrease forest water supply, increase irrigation water demand and negatively effect on cropland stability and productivity (Lim et al., 2017a; Lim et al., 2019b).

Knowledge gaps: Despite getting attention at the global, regional, national and sub-national agenda, there are many challenges remain in both scientific research and policy actions. The scientific challenges include data, information and knowledge gaps in understanding food energy water and land interlinkages, and lack of systematic tools to address trade-offs (Liu et al., 2017a). Until very recently, implementation of food energy water nexus focused primarily on technical solutions, whereas governance, i.e. the institutions and processes governing the WEF nexus, has not received much consideration (Scheyvens and Shivakoti, 2019). At the policy end, the common challenges for implementation of water energy food land nexus are absence of sectoral coordination (Pahl-Wostl, 2019); the influence of political priorities on decisions and lack of processes for scientific knowledge to shape decisions; lack of capacity to understand interlinkages between sectors; lack of multistakeholder engagement in planning and decision-making processes; and lack of incentive mechanisms and adequate finance to support the approach (Bao et al., 2018; Scheyvens and Shivakoti, 2019).

10.6.4 Social Justice and Equity

Social justice focuses on justice-related implications of social and economic institutions, examined in different ways such as distributional justice (distribution of benefits and burdens across different societal groups; procedural justice (the design of just institutions and processes for decision-making); inter-generational justice (duties of justice to future generations); and recognitional justice (recognition of historical inequality) (Thaler et al., 2017). Climate change is affecting every aspect of our society and economy, thus it is pertinent to understand the interactions between social justice and climate change impacts (Tol, 2018). In particular focusing on how vulnerability to various impacts is created, maintained and distributed across geographical, social, demographic and economic dimensions (Bulkeley et al., 2014; Schlosberg and Collins, 2014; Van de Vliert, 2014; Burke et al., 2016). For instance, environmental and health consequences of climate change, which disproportionately affect low-income countries and poor people in high-income countries, profoundly affect human rights and social justice (Levy and Patz, 2015). Furthermore, great concern is expressed about the plight of the poor, disadvantaged and vulnerable populations when it comes to climate but not in other policy domains (Winters, 2014).

Evidence is increasing on the importance of focusing on environmental sustainability and relieving poverty and social injustice are not conflicting aims, in fact there is a further need for mainstreaming such approaches in order to respond to the climate change challenge in a socially just manner (Mayrhofer and Gupta, 2016). These not conflicting aims are described as co-benefits as reiterated in the IPCC reports as a central concept that refers to 'the positive effects that a policy or measure aimed at one objective might have on other objectives, irrespective of the net effect on overall social welfare' (IPCC, 2014b). Better understanding of how social justice affects and is affected by efforts to build adaptive capacity will be crucial to avoiding unintended and even perverse outcomes. For example, in Andaman coast of Thailand, responses to climate change trends and events tended to be reactive rather than proactive, making already vulnerable people even more vulnerable and undermining their capacity to adapt in the future (Bennett et al., 2014). Different forms of inequality, moreover, render some groups of people more vulnerable than others to damage from climate hazards. In Mumbai, India, for example, the houses of poorer families required repeated repairs to secure them against flood damage, and the cumulative cost of those repairs consumed a greater proportion of their income than for richer populations (UN, 2016). Building the resilience of vulnerable groups requires strong community and government institutions that can support efforts to cope with devastating events, offering social protection and social development initiatives to support at-risk or vulnerable groups (Drolet et al., 2015). In addition, agencies need to consider how they can best work in ways which potentially support longer-term positive change to gender roles and relations, such as post-disaster activities must build and resource women's resilience and adaptive capacity in practice and challenge the constraints that impinge on their lives (Alam and Rahman, 2019) (Hadiyanto et al., 2018) (Yumarni and Amaratunga, 2018) (Sohrabizadeh et al., 2016) (Sadia et al., 2016).

Insights from the environmental justice literature show that an over-emphasis on emission reductions at national levels obscures negative impacts on disadvantaged communities, including low-income communities (Burch and Harris, 2014). The issue of social justice and adaptation is particularly relevant because of the politics that drive how adaptation and recovery efforts and investments are targeted towards specific populations, places, and capacities (Klinsky et al., 2017). Hence, climate justice and equity need to be highlighted more explicitly in integrative approaches to mitigation and adaptation (Moellendorf, 2015; Henrique KP, 2020) (*medium evidence, high agreement*).

The term climate justice is used to problematise global warming in ethical and political contexts. It does so by employing the concepts of environmental justice and social justice to examine inequalities and violation of human/collective rights in relation to climate change impacts (Ghimire, 2016)

At the heart of climate justice concerns lies the asymmetry that those who have contributed least to the problem of climate change i.e. greenhouse gas (GHG) emissions are the ones who will be affected by its adverse impacts the most. It is about sharing the burden and benefits equitably – i) among developed and developing countries in the context of historical responsibility, and ii) within nations to uplift the marginalised and affected populations who have contributed the least to the problem in the contexts of per-capita equity and local vulnerability (Joshi, 2014; Chaudhuri, 2020; Shawoo, 2020).

An ethical analysis of the climate regime reveals an abiding strong interconnection between economic circumstances, geopolitical power and the justice claims that nations can assert in negotiations (Okereke, 2016). Events within the climate regime highlight the importance of questioning the extent to which claims of justice can ever be truly realised in the context of international regimes of environmental governance as well as how much concerns for justice are motivated by other con- cerns such as relative economic gains or geopolitical objectives (Sikor T, 2014) .

The global land rush and mainstream climate change narratives have broadened the ranks of state and social actors concerned about land issues, while strengthening those opposed to social justice-oriented land policies (Borras, 2018).The five deep social reforms (redistribution, recognition, restitution, regeneration and resistance) of socially just land policy are necessarily intertwined. But the global land rush amidst deepening climate change calls attention to the linkages, especially between the pursuit of agrarian justice on the one hand and climate justice on the other. Here, the relationship is not without contradictions, and warrants increased attention as both unit of analysis and object of political action. Understanding and deepening agrarian justice imperatives in climate politics, and understanding and deepening climate justice imperatives in agrarian politics, is needed more than ever in the ongoing pursuit of alternatives. For example, the intersection between land grabs and climate change mitigation politics in Myanmar has created new political opportunities for scaling up, expanding and deepening struggles toward ‘agrarian climate justice’(Sekine, 2021).

[START FAQ10.1 HERE]

FAQ 10.1: What are the current and projected key risks related to climate change in each sub-region of Asia?

Climate change related risks are projected to increase progressively at 1.5°C, 2°C and 3°C of global warming in many parts of Asia. Heat stress and water deficit are affecting human health and food security. Risks due to extreme rainfall and sea level rise are exacerbating in vulnerable Asia.

Climatologically, the summertime surface air temperature in South, Southeast and Southwest Asia is high, and its coastal area is very humid. In these regions, heat stress is already a medium risk for humans. Large cities are warmer more than 2°C compared to the surroundings due to heat island effects, exacerbating heat stress conditions. Future warmings will cause more frequent temperature extremes and heat waves especially in densely populated South Asian cities, where working conditions will be exacerbated and day-time outdoor work becomes danger. For example, incidence of excess heat-related mortality in 51 cities in China is estimated to reach 37,800 deaths per year over a 20-year period in the mid-21st century (2041–2060) under the RCP 8.5 scenario.

Asian glaciers are the water resources for local and adjacent regions. Glaciers are decreasing in Central, Southwest, Southeast and North Asia, but are stable or increased in some parts of Hindu Kush-Himalaya. The glacier melt water in southern Tibetan Plateau has increased during 1998-2007, and the total amount and area of glacier lakes increased during last decades. In the future, maximum glacial runoff is projected in High Mountain Asia. Glacier collapses and surges, together with glacier lake outburst flood (GLOF) due to the expansion of glacier lakes, will threaten the securities of the local and down streaming societies. The glacier is *likely* to disappear by nearly 50% in High Mountain Asia and about 70% in Central and Western Asia by the end of the 21st century under the RCP4.5 scenario, and more under the RCP8.5 scenario.

As a large number of populations is living in the drought-prone areas, water scarcity is a prevailing risk across Asia through water and food shortage leading to malnutrition. Population vulnerable to impacts related to water is going to increase progressively at 1.5°C, 2°C and 3°C of global warming. Aggravating drought condition is projected in Central Asia. Water quality degradation also has profound impact on human health.

Extreme rainfall causes floods in vulnerable rivers. Observed changes in extreme rainfall vary considerably region by region in Asia. Extreme rainfall events (such as heavy rainfall > 100 mm day^{-1}) have been increasing in South and East Asia. In the future, most of East and Southeast Asia are projected to experience more intense rainfall events as soon as by the middle of the 21st century. In those regions, the flood risk will become more frequent and severe. It is estimated that over 1/3rd Asian cities and about 932 million urban dwellers are living in areas with high risk of flooding.

Sea level rise is continuing. Higher than the global mean sea level rise is projected in Asian coasts. Storm surge and high wave by tropical cyclones of higher intensity are high risk for a large number of Asian mega-cities facing the ocean; China, India, Bangladesh, Indonesia and Viet Nam have the highest numbers of coastal populations exposed, thus most vulnerable disaster-related mortality.

Changes in terrestrial biome are observed that are consistent with warming, such as an upward move of treeline position in mountains. Climate change, human activity, lightning and quality of forest governance and management determine increase of wildfire severity and area burned in North Asia last decades. Changes in marine primary production are also observed. Up to 20% decrease over the past six decades in the Western Indian Ocean due to ocean warming and stratification restricts nutrient mixing. The risk of irreversible loss of many ecosystems will increase with global warming.

The likelihood of adverse impacts to agricultural and food security in many parts of developing Asia will progressively escalate with the changing climate. Potential of total fisheries production in South and Southeast Asia is also projected to decrease.

Figure FAQ10.1 Key risks related climate change in Asia.

[START FAQ10.2 HERE]

FAQ 10.2: What are current and emerging adaptation options across Asia?

Mirroring the heterogeneity across Asia, different countries and communities are undertaking a range of reactive and proactive strategies to manage risk in various sectors. Several of these adaptation actions show promise; reducing vulnerability and improving societal wellbeing. However, challenges remain around scaling up adaptation actions in a manner that is effective and inclusive while simultaneously meeting national development goals.

Asia exhibits tremendous variation in terms of ecosystems, economic development, cultures, and climate risk exposure. Mirroring this variation, households, communities, and governments have a wide range of coping and adaptation strategies to deal with changing climatic conditions, with co-benefits for various non-climatic issues such as poverty, conflict, and livelihood dynamics.

Currently, Asian countries have rich evidence on managing risk, drawing on long histories of dealing with change. For example, to deal with erratic rainfall and shifting monsoons, farmers make incremental shifts such as changing what and when they grow or adjusting their irrigation practices. Communities living in coastal settlements are using early warning systems to prepare for cyclones or raising the height of their houses to minimize flood impacts. These types of strategies, seen across all Asian sub-regions, based on local social and ecological contexts, are termed *autonomous adaptations* that occur incrementally and help people manage current impacts.

Currently and in the future, Asia is identified as one of regions most vulnerable to climate change, especially on extreme heat, flooding, sea level rise, and erratic rainfall. All these climatic risks, when overlaid on existing development deficits show us that incremental adaptation will not be enough, transformational change is required. Recognizing this, at sub-national and national levels, government and non-governmental actors are also prioritizing *planned adaptation strategies* which include interventions like 'climate-smart agriculture' as seen in South and South East Asian countries or changing labour laws to reduce exposure to heat as seen in West Asia. These are often sectoral priorities governments lay out through national or subnational policies and projects, drawing on various sources of funding: domestic, bilateral, and international. Apart from these planned adaptation strategies in social systems, Asian countries also report and invest in adaptation measures in natural systems such as expanding nature reserves to enable species conservation; or setting up habitat corridors to facilitate landscape connectivity and species movements across climatic gradients.

Overall, the fundamental challenges that Asia will see exacerbate under climate change are around water and food insecurity, poverty and inequality, and increased frequency and severity of extreme events. In some places and for some people, climate change, even at 1.5°C and more so at 2°C, will significantly constrain the functioning and wellbeing of human and ecological systems. Asian cities, villages, and countries are rising to this current and projected challenge, albeit somewhat unevenly.

Some examples of innovative adaptation actions are China's Sponge Cities which are trying to protect ecosystems while reduce risk for people, now and in the future. Another example is India's Heat Action Plans that are using 'cool roofs' technologies and awareness building campaigns to reduce impacts of extreme heat. Across South and Southeast Asia, climate-smart agriculture programmes are reducing greenhouse gas emissions associated with farming while helping farmers adapt to changing risks. Each country is experimenting with infrastructural, nature-based, technological, institutional, and behavioral strategies to adapt to current and future climate change with local contexts shaping both the possibility of undertaking such actions as well as the effectiveness of these actions to reduce risk. What works for aging cities in Japan exposed to heatwaves and floods may not work for pastoral communities in the highlands of Central Asia but there is progress on understanding what actions work and for whom. The challenge is to scale current adaptation action, especially in most exposed areas and for most vulnerable populations, as well as move beyond adapting to single risks alone (i.e. adapt to multiple coinciding risks such as flooding and water scarcity in coastal cities across South Asia or extreme heat and flash floods in West Asia). In this context, funding and implementing adaptation is essential and while Asian countries are experimenting with a range of autonomous and planned adaptation actions to deal with these multiple and often concurrent challenges, making current development pathways climate-resilient is necessary and, some might argue, unavoidable.

Table FAQ10.2.1: System transitions, sectors, and illustrative adaptation options.

System transitions	Sectors	Illustrative adaptation options
Energy and industrial systems	Energy and industries	• Diversifying energy sources • Improving energy access, especially in rural areas • Improving resilience of power infrastructure • Rehabilitation and upgrading of old buildings
Land and ecosystems	Terrestrial and freshwater ecosystems	• Expanding nature reserves • Assisted species migration • Introducing species to new regions to protect from climate-induced extinction risk • Sustainable forest management including afforestation, forest fuel management, fire management
	Ocean and coastal ecosystems	• Marine protected areas • Mangrove and coral reef restoration • Integrated coastal zone management • Sand banks and structural technologies
	Freshwater	• Integrated watershed management • Transboundary water management • Changing water access and use practices to reduce/manage water demand • High efficiency water-saving technology • Aquifer storage and recovery
	Agriculture, fisheries, and food	• Changing crop type and variety, improving seed quality • Water storage, irrigation and water management • Climate-smart agriculture • Early warning systems and use of climate information services • Fisheries management plans (e.g., seasonal closures, limited fishing licenses, livelihood diversification)

Urban systems	Cities, settlements and	• Flood protection measures and sea walls • sustainable land use planning and regulation • Protecting urban green spaces, improving permeability, mangrove restoration in coastal cities • Planned relocation and migration • Disaster management and contingency planning
	Key infrastructures	• climate-resilient highways and power infrastructure • relocating key infrastructure
Health systems		• Reducing air pollution • Changing dietary patterns

[END FAQ10.2 HERE]

[START FAQ10.3 HERE]

FAQ 10.3: How is Local Knowledge and Indigenous Knowledge being incorporated in the design and implementation of adaptation projects and policies in Asia?

Indigenous People, comprising about six percent of the global population, play a crucial role in managing climate change for two important reasons, first, they have a physical and spiritual connection with land, water and associated ecosystems, thus making them most vulnerable to any environmental and climatic changes. Second, their ecological and local knowledge are relevant to finding solutions to climate changes.

Local Knowledge and Indigenous Knowledge (LIK) play an important role in the formulation of adaptation governance and related strategies (IPCC 2007), and best quality, locality specific knowledge can help address serious lack of education on climate change and uncertainties surrounding quality, salience, credibility and legitimacy of available knowledge base.

Key findings across Asia, underline the importance of building, sustaining and augmenting local capacity through addressing inadequacies in terms of resource base, climate change awareness, government-community partnerships, and vulnerability assessment. Furthermore, inclusion of Local Knowledge and Indigenous Knowledge as well as practices will improve adaptation planning and decision-making process to climate change.

In climate sensitive livelihoods, integrated approach informed by science that examines multiple stressors along with LIK appears to be of immense value. For instance in building farmers' resilience, enhancing climate change adaptation, ensuring cross cultural communication, and promoting local skills are drawing upon Indigenous People's intuitive thinking processes and geographical knowledge of remote areas.

There is also a widespread recognition that Local Knowledge and Indigenous Knowledge are important in ensuring successful ecosystem-based adaptation (EbA). However, this recognition requires more practical and translation into LIK driven EbA projects. For instance, in the Coral Triangle region, creating historical timelines and mapping seasonal calendars can help to capture LIK while also feeding this information into climate science and climate adaptation planning. Identifying indigenous crop species for agriculture by using LIK is already identified as an important way to localise climate adaptation, an example observed from Bali's vital contribution of moral economies to food systems have long build resilience among groups of communities in terms of food security and sovereignty even with challenges faced due to modernizing of local food systems.

Many of the pressing problems of Asia, including water scarcity, rapid urbanisation, deforestation, loss of species, rising coastal hazards, agricultural loss can be effectively negated, or at least minimised through proper adoption of suitable science and technological method. Climate change adaptation is greatly facilitated by science, technology and innovation. This ranges from application of existing science, new development on scientific tools and methods, application of LIK and citizen sciences. Deploying Knowledge Quality Assessment Tool found significant co-relation between science-based and LIK framing would help to address, acknowledge, and utilise integrated approach in showing how the respect to this wisdom of LIK, a valuable asset for climate adaptation governance. LIK based environmental indicators need to be seen as part of a separate system of knowledge that coexists with, but is not submerged into, another conventional knowledge system.

In the context of education and capacity development of climate change, integrated approach of embracing both the importance of climate science and LIK is acknowledged. The LIK is increasingly recognised as a powerful tool for compiling evidence of climate change over time. Such as knowledge of climate change adaptation (CCA) and disaster risk reduction (DRR) provide a range of complementary approaches in building resilience and reducing vulnerability of natural and human systems. Developing knowledge and utilising existing Local Knowledge and Indigenous Knowledge, skills, and dispositions to better cope with already evident and looming climate impacts. Engaging communities in the process of documenting and understanding long-term trends and practices will enable both Local Knowledge and Indigenous Knowledge as well as Western scientific assessments of change in designing appropriate climate adaptation measures.

[END FAQ10.3 HERE]

[START FAQ10.4 HERE]

FAQ 10.4: How can Asia meet multiple goals of climate change adaptation and sustainable development within the coming decades?

Asian countries are testing ways to develop in a climate resilient manner to meet goals of climate change and sustainable development simultaneously. Some promising examples exist but the window of opportunity to put some of these plans in place is small and reducing, highlighting the need for urgent action across and within countries.

In order to achieve multiple goals of climate change adaptation, mitigation, and sustainable development; rapid, system transitions across energy systems; land and ecosystems; urban and infrastructural systems; are critical. This is especially important across Asia, which has the largest population exposed to current climate risks, high sub-regional diversity, and where risks are expected to rise significantly and unevenly under higher levels of global warming. However, such transformational change is deeply challenging because of variable national development imperatives; differing capacities and requirements of large, highly unequal, and vulnerable populations; and socio-economic and ecological diversity that requires very contextual solutions. Further, issues such as growing transboundary risks, inadequate data for long-term adaptation planning, finance barriers, uneven institutional capacity, and non-climatic issues such as increasing conflict, political instability, and polarization, constrain rapid, transformational action across systems.

Despite these challenges, there are increasing examples of action across Asia that are meeting climate adaptation and sustainable development goals simultaneously such as through climate smart agriculture, disaster risk management, and nature-based solutions. To enable these system transitions, vertical and horizontal policy linkages; active communication and cooperation between multiple stakeholders; and attention to the root causes of vulnerability are essential Further, rapid systemic transformation can be enabled by policies and finances to incentivize capacity building, new technological innovation and diffusion. The effectiveness of such technology-centric approaches can be maximized by combining with attention to behavioral shifts such as by improving education and awareness, building local capacities and institutions, and leveraging Indigenous and local knowledge.

The window of opportunity to act is small and reducing; if system transitions are delayed, there is high confidence that climatic risks will increase human and natural system vulnerability as well as increase inequality and erode achievement of multiple SDGs. Thus, urgent, systemic change that is suited to national and sub-national socio-ecological contexts across Asia is imperative.

Adaptation option	Mitigation impacts	Implications on SDGs	
		Positive	Negative
Wetland protection, restoration	Medium synergy (carbon sequestration through mangroves)	8, 14, 15	
Solar drip irrigation	High synergy (shift to cleaner energy)	2, 7, 12	10
Climate-smart agriculture	High synergy (no till practices and improved residue management can reduce soil carbon emissions)	2, 12	
Integrated smart water grids	High synergy (reduced energy needs for supplying water)	6, 9, 11	
Disaster risk management (including early warning systems)	Not applicable	9, 11	5, 10
Aquifer storage and recovery	Low synergy	6, 12	
Nature-based solutions in urban areas: green infrastructure	High synergy (blue-green infrastructure act as carbon sinks)	3, 9, 11	
Coastal green infrastructure	High synergy	9, 11, 14, 15

Chapter 11: Australasia

Coordinating Lead Authors: Judy Lawrence (New Zealand) and Brendan Mackey (Australia)

Lead Authors: Francis Chiew (Australia), Mark J. Costello (New Zealand/Norway/Ireland), Kevin Hennessy (Australia), Nina Lansbury (Australia), Uday Bhaskar Nidumolu (Australia), Gretta Pecl (Australia), Lauren Rickards (Australia), Nigel Tapper (Australia), Alistair Woodward (New Zealand), Anita Wreford (New Zealand)

Contributing Authors: Jason Alexandra (Australia), Anne-Gaelle Ausseil (New Zealand), Shaun Awatere (New Zealand), Douglas Bardsley (Australia), Rob Bell (New Zealand), Paula Blackett (New Zealand), Sarah Boulter (Australia), Nicholas Cradock-Henry (New Zealand), Sandra Creamer (Australia), Rebecca Darbyshire (Australia), Sam Dean (New Zealand), Alejandro Di Luca (Australia/Canada), Andrew Dowdy (Australia), Joanna Fountain (New Zealand), Michael Grose (Australia), Stefan Hajkowicz (Australia), David Hall (New Zealand), Sarah Harris (Australia), Peter Hayman (Australia), Jane Hodgkinson (Australia), Karen Hussey (Australia), Rhys Jones (New Zealand), Darren King (New Zealand), Martina Linnenluecke (Australia), Erich Livengood (New Zealand), Mary Livingston (New Zealand), Cate MacInnis-Ng (New Zealand), Belinda McFadgen (New Zealand), Celia McMichael (Australia), Bradley Moggridge (Australia), Sandy Morrison (New Zealand), Vinnitta Mosby (Australia), Esther Onyango (Australia/Kenya), Sharanjit Paddam (Australia), Grant Pearce (New Zealand), Petra Pearce (New Zealand), Rosh Ranasinghe (Netherlands), David Schoeman (Australia), Rodger Tomlinson (Australia), Michael Watt (New Zealand), Seth Westra (Australia), Russell Wise (Australia).

Review Editors: Ove Hoegh-Guldberg (Australia), David Wratt (New Zealand)

Chapter Scientists: Belinda McFadgen (New Zealand), Esther Onyango (Australia/Kenya)

Date of Draft: 1 October 2021

Notes: TSU Compiled Version

Table of Contents

Executive Summary

Observed changes and impacts

Ongoing climate trends have exacerbated many extreme events (*very high confidence*). The Australian trends include further warming and sea-level rise, with more hot days and heatwaves, less snow, more rainfall in the north, less April-October rainfall in the south-west and south-east, more extreme fire weather days in the south and east. The New Zealand trends include further warming and sea-level rise, more hot days and heatwaves, less snow, more rainfall in the south, less rainfall in the north, and more extreme fire weather in the east. There have been fewer tropical cyclones and cold days in the region. Extreme events include Australia's hottest and driest year in 2019 with a record-breaking number of days over 39ºC, New Zealand's hottest year in 2016, three widespread marine heatwaves during 2016-2020, Category 4 cyclone Debbie in 2017, seven major hailstorms over eastern Australia and two over New Zealand from 2014-2020, three major floods in eastern Australia and three over New Zealand during 2019-2021, and major fires in southern and eastern Australia during 2019-2020. {11.2.1, Table 11.2, 11.3.8}

Climate trends and extreme events have combined with exposure and vulnerabilities to cause major impacts for many natural systems, with some experiencing or at risk of irreversible change in Australia (*very high confidence)* and in New Zealand *(high confidence).* For example, warmer conditions with more heatwaves, droughts and catastrophic wildfires have negatively impacted terrestrial and freshwater ecosystems. The Bramble Cay melomys, an endemic mammal species, became extinct due to loss of habitat associated with sea-level rise and storm surges in the Torres Strait. Marine species abundance and distributions have shifted polewards, and extensive coral bleaching events and loss of temperate kelp forests have occurred, due to ocean warming and marine heatwaves across the region. In New Zealand's Southern Alps, from 1978-2016, the area of 14 glaciers declined 21%, and extreme glacier mass loss was at least six times more likely in 2011, and ten times more likely in 2018, due to climate change. The end-of-summer snowline elevation for 50 glaciers rose 300 m from 1949-2019. {11.3.1.1, 11.3.2.1, Table 11.2b, Table 11.4, Table 11.6, Table 11.9}

Climate trends and extreme events have combined with exposure and vulnerabilities to cause major impacts for some human systems (*high confidence*). Socio-economic costs arising from climate variability and change have increased. Extreme heat has led to excess deaths and increased rates of many illnesses. Nuisance and extreme coastal flooding have increased due to sea-level rise superimposed upon high tides and storm surges in low-lying coastal and estuarine locations, including impacts on cultural sites, traditions and lifestyles of Aboriginal and Torres Strait Islander Peoples in Australia and Tangata Whenua Māori in New Zealand. Droughts have caused financial and emotional stress in farm households and rural communities. Tourism has been negatively affected by coral bleaching, fires, poor ski seasons and receding glaciers. Governments, business and communities have experienced major costs associated with extreme weather, droughts and sea-level rise. {11.3, 11.4, 11.5.2, Table 11.2, Boxes 11.1-11.6}

Climate impacts are cascading and compounding across sectors and socio-economic and natural systems *(high confidence)*. Complex connections are generating new types of risks, exacerbating existing stressors and constraining adaptation options. An example is the impacts that cascade between interdependent systems and infrastructure in cities and settlements. Another example is the 2019-2020 south-eastern Australian wildfires which burned 5.8 to 8.1 million hectares, with 114 listed threatened species losing at least half of their habitat and 49 losing over 80%, over 3,000 houses destroyed, 33 people killed, a further 429 deaths and 3230 hospitalizations due to cardiovascular or respiratory conditions, $1.95 billion in health costs, $2.3 billion in insured losses, and $3.6 billion in losses for tourism, hospitality, agriculture and forestry. {11.5.1, Box 11.1}

Increasing climate risks are projected to exacerbate existing vulnerabilities and social inequalities and inequities *(high confidence)*. These include inequalities between Indigenous and non-Indigenous Peoples, and between generations, rural and urban areas, incomes and health status, increasing the climate risks and adaptation challenges faced by some groups and places. Resultant climate change impacts include the displacement of some people and businesses, and threaten social cohesion and community wellbeing. {11.3.5, 11.3.6, 11.3.10, 11.4}

Projected impacts and key risks

Further climate change is inevitable, with the rate and magnitude largely dependent on the emission pathway (*very high confidence*[1]). Ongoing warming is projected, with more hot days and fewer cold days (*very high confidence*). Further sea-level rise, ocean warming and ocean acidification are projected (*very high confidence*). Less winter and spring rainfall is projected in southern Australia, with more winter rainfall in Tasmania, less autumn rainfall in south-western Victoria and less summer rainfall in western Tasmania (*medium confidence*), with uncertain rainfall changes in northern Australia. In New Zealand, more winter and spring rainfall is projected in the west and less in the east and north, with more summer rainfall in the east and less in the west and central North Island (*medium confidence*). In New Zealand, ongoing significant clean ice glacier retreat is projected (*very high confidenc*e). More droughts and extreme fire weather are projected in southern and eastern Australia (*high confidence*) and over most of New Zealand (*medium confidence*). Increased rainfall intensity is projected, with fewer tropical cyclones and a greater proportion of severe cyclones *(medium confidence*). {11.2.2, Table 11.3, Box 11.6}

Climate risks are projected to increase for a wide range of systems, sectors and communities, which are exacerbated by underlying vulnerabilities and exposures (*high confidence*) {11.3; 11.4}. Nine key risks were identified, based on magnitude, likelihood, timing and adaptive capacity {11.6, Table 11.14}:

Ecosystems at critical thresholds, where recent climate change has caused significant damage and further climate change may cause irreversible damage, with limited scope for adaptation

Loss and degradation of coral reefs and associated biodiversity and ecosystem service values in Australia due to ocean warming and marine heatwaves, e.g. three marine heatwaves on the Great Barrier Reef during 2016-2020 caused significant bleaching and loss. {11.3.2.1, 11.3.2.2, Box 11.2}

Loss of alpine biodiversity in Australia due to less snow, e.g. loss of alpine vegetation communities (snow patch Feldmark and short alpine herb-fields) and increased stress on snow-dependent plant and animal species, {11.3.1.1, 11.3.1.2}

Key risks that have potential to be severe but can be reduced substantially by rapid, large-scale and effective mitigation and adaptation

Transition or collapse of alpine ash, snowgum woodland, pencil pine and northern jarrah forests in southern Australia due to hotter and drier conditions with more fires, e.g. declining rainfall in southern Australia over the past 30 years has led to drought-induced canopy dieback across a range of forest and woodland types, and death of fire-sensitive tree species due to unprecedented wildfires. {11.3.1.1, 11.3.1.2}

Loss of kelp forests in southern Australia and southeast New Zealand due to ocean warming, marine heatwaves and overgrazing by climate-driven range extensions of herbivore fish and urchins, e.g. less than 10% of giant kelp in Tasmania was remaining by 2011 due to ocean warming. {11.3.2.1, 11.3.2.2}

Loss of natural and human systems in low-lying coastal areas due to sea-level rise, e.g. for 0.5 m sea-level rise, the value of buildings in New Zealand exposed to 1-in-100 year coastal inundation could increase by NZ$12.75 billion and the current 1-in-100 year flood in Australia could occur several times a year. {11.3.5; Box 11.6}

Disruption and decline in agricultural production and increased stress in rural communities in south-western, southern and eastern mainland Australia due to hotter and drier conditions, e.g. by 2050, a decline in median wheat yields of up to 30% in south-west Australia and up to 15% in South Australia, and increased heat stress in livestock by 31–42 days per year. {11.3.4; 11.3.5; Box 11.3}

[1] In this Report, the following summary terms are used to describe the available evidence: limited, medium, or robust; and for the degree of agreement: low, medium, or high. A level of confidence is expressed using five qualifiers: very low, low, medium, high, and very high, and typeset in italics, e.g., *medium confidence*. For a given evidence and agreement statement, different confidence levels can be assigned, but increasing levels of evidence and degrees of agreement are correlated with increasing confidence.

Increase in heat-related mortality and morbidity for people and wildlife in Australia due to heatwaves, e.g. heat-related excess deaths in Melbourne, Sydney and Brisbane are projected to increase by about 300/year (low emission pathway) to 600/year (high emission pathway) during 2031-2080 relative to 142/year during 1971-2020. {11.3.1, 11.3.5.1, 11.3.5.2, 11.3.6.1, 11.3.6.2}

Key cross-sectoral and system-wide risk

Cascading, compounding and aggregate impacts on cities, settlements, infrastructure, supply-chains and services due to wildfires, floods, droughts, heatwaves, storms and sea-level rise, e.g. in New Zealand, extreme snow, heavy rainfall and wind events have combined to impact road networks, power and water supply, interdependent wastewater and stormwater services and business activities {11.3.3, 11.5.1, 11.8.1}.

Key implementation risk

Inability of institutions and governance systems to manage climate risks, e.g. the scale and scope of projected climate impacts overwhelm the capacity of institutions, organisations and systems to provide necessary policies, services, resources and coordination to address the socio-economic impacts {11.5.1.2, 11.5.1.3, 11.5.2.3, 11.6, 11.7.1, 11.7.2, 11.7.3}.

There are important interactions between mitigation and adaptation policies and their implementation *(high confidence)*. Integrated policies in interdependent systems across biodiversity, water quality, water availability, energy, transport, land use and forestry for mitigation, can support synergies between adaptation and mitigation. These have co-benefits for the management of land use, water and associated conflicts, and for the functioning of cities and settlements. For example, projected increases in fire, drought, pest incursions, storms and wind place forests at risk and affect their ongoing role in meeting New Zealand's emissions reduction goals. {11.3.4.3, 11.3.10.2, 11.3.5.3, Box 11.5}

Challenges and solutions

The ambition, scope and progress of the adaptation process has increased across governments, non-government organisations, businesses and communities (*high confidence*). This process includes vulnerability and risk assessments, identification of strategies and options, planning, implementation, monitoring, evaluation and review. Initiatives include institutional frameworks in statute for risk assessment and national adaptation planning and monitoring in New Zealand, a National Recovery and Resilience Agency and National Disaster Risk Reduction Framework in Australia, deployment of new national guidance, decision tools, collaborative governance approaches, and the introduction of climate risk and disclosure regimes for the private sector. The focus however has been on adaptation planning, rather than on implementation. {11.5.1, 11.7.1.1, Box 11.6, Table 11.15a, Table 11.15b, Table 11.17}

Adaptation progress is uneven, due to gaps, barriers and limits to adaptation, and adaptive capacity deficits (*very high confidence*). Progress in adaptation planning, implementation, monitoring and evaluation is lagging. Barriers include lack of consistent policy direction, competing objectives, divergent risk perceptions and values, knowledge constraints, inconsistent information, fear of litigation, up-front costs, and lack of engagement, trust and resources. Adaptation limits are being approached for some species and ecosystems. Adaptive capacity to address the barriers and limits can be built through greater engagement with groups and communities to build trust and social legitimacy through inclusion of diverse values, including those of Aboriginal and Torres Strait Islander Peoples and Tangata Whenua Māori. {11.4, 11.5, 11.6, 11.7, 11.8, Table 11.4, Table 11.5, Table 11.6, Table 11.16, Box 11.2}

A range of incremental and transformative adaptation options and pathways is available as long as enablers are in place to implement them (*high confidence*). Key enablers for effective adaptation include shifting from reactive to anticipatory planning, integration and coordination across levels of government and sectors, inclusive and collaborative institutional arrangements, government leadership, policy alignment, nationally consistent and accessible information, decision-support tools, along with adaptation funding and finance and robust consistent and strategic policy commitment. Over three-quarters of people in Australia and New Zealand agree that climate change is occurring and over 60% believe climate change is caused by humans, giving climate adaptation and mitigation action further social legitimacy. {11.7.3, Table 11.17}

New knowledge on system complexity, managing uncertainty and how to shift from reactive to adaptive implementation is critical for accelerating adaptation (*high confidence*). Priorities include: greater understanding of impacts on natural system dynamics; the exposure and vulnerability of different groups within society, including Indigenous Peoples; the relationship between mitigation and adaptation; the effectiveness and feasibility of different adaptation options; the social transitions needed for transformative adaptation; and the enablers for new knowledge to better inform decision making, e.g. monitoring data repositories, risk and vulnerability assessments, robust planning approaches, sharing adaptation knowledge and practice. {11.7.3.3}

Aboriginal and Torres Strait Islander Peoples and Tangata Whenua Māori can enhance effective adaptation through the passing down of knowledge about climate change planning that promotes collective action and mutual support across the region (*high confidence*). Supporting Aboriginal and Torres Strait Islander Peoples and Tangata Whenua Māori institutions, knowledge and values, enables self-determination and creates opportunities to develop adaptation responses to climate change. Actively upholding the UN Declaration on the Rights of Indigenous Peoples and Māori interests under the Treaty of Waitangi at all levels of government enables intergenerational approaches for effective adaptation. {11.3, 11.4, 11.6, 11.7.3; Cross-Chapter Box INDIG in Chapter 18}

A step change in adaptation is needed to match the rising risks and to support climate resilient development *(very high confidence*). Current adaptation is largely incremental and reactive. A shift to transformative and proactive adaptation can contribute to climate resilient development. The scale and scope of cascading, compounding and aggregate impacts require new, larger-scale and timely adaptation. Monitoring and evaluation of the effectiveness of adaptation progress and continual adjustment is critical. The transition to climate-resilient development pathways can generate major co-benefits, but complex interactions between objectives can create trade-offs. {11.7, 11.8.1, 11.8.2}

Delay in implementing adaptation and emission reductions will impede climate resilient development, resulting in more costly climate impacts and greater scale of adjustments (*very high confidence*). The region faces an extremely challenging future. Reducing the risks would require significant and rapid emission reductions to keep global warming to 1.5-2.0ºC, as well as robust and timely adaptation. The projected warming under current global emissions reduction policies would leave many of the region's human and natural systems at very high risk and beyond adaptation limits. {11.8, Table 11.1, Table 11.14, Figure 11.6}

11.1 Introduction

This chapter assesses observed impacts, projected risks, vulnerability and adaptation, and the implications for climate resilient development for the Australasia region, based on literature published up to 1 September 2021. It should be read in conjunction with other Working Group 2 chapters, the climate science assessment in the Working Group 1 Report and the greenhouse gas emissions and mitigation assessment in the Working Group 3 Report.

11.1.1 Context

The Australasia region is defined as the Exclusive Economic Zones (EEZ) and territories of Australia and New Zealand. In both countries, climate adaptation is largely implemented at a sub-national level through devolution of functions constitutionally or by statute, alongside disaster risk reduction (COAG, 2011; Lawrence et al., 2015; Macintosh et al., 2015).

Australia's economy is dominated by financial and insurance services, education, mining, construction, tourism, health care and social assistance (ABS, 2018) with Australian exports accruing mostly from mining (ABS, 2018; ABS, 2019). In New Zealand, service industries, including tourism, collectively account for around two thirds of GDP (NZ Treasury, 2016). The primary sector contributes 6% of New Zealand's GDP and over half of the country's export earnings (NZ Treasury, 2016).

Existing vulnerabilities expose and exacerbate inequalities between rural, regional and urban areas, Indigenous and non-Indigenous Peoples, those with health and disability needs, and between generations, incomes and health status, increasing the relative climate change risk faced by some groups and places (Jones et al., 2014; Bertram, 2015; Perry, 2017; Hazledine and Rashbrooke, 2018) (*high confidence*).

Previous IPCC reports (Table 11.1) have documented observed climate impacts, projected risks, adaptation challenges and opportunities. In this chapter, there is more evidence of observed climate impacts and adaptation, better quantification of socio-economic risks, new information about cascading and compounding risks, greater emphasis on adaptation enablers and barriers, and links to climate-resilient development.

Table 11.1: Summary of key conclusions from the IPCC 5th Assessment Report (AR5) Australasia chapter (Reisinger et al., 2014) and relevant conclusions from the IPCC Special Reports on Global Warming of 1.5°C (IPCC, 2018), Climate Change and Land (IPCC, 2019a) and Oceans and Cryosphere (IPCC, 2019b)

Conclusions	Report
Our regional climate is changing (*very high confidence*) and warming will continue through the 21st century (*virtually certain*) with more hot days, fewer cold days, less snow, less rainfall in southern Australia and the northeast of both of New Zealand's islands, more rainfall in western New Zealand, more extreme rainfall, sea-level rise, increased fire weather in southern Australia and across New Zealand, and fewer cyclones but a greater proportion of intense cyclones. Key risks include changes in the structure and composition of Australian coral reefs, loss of montane ecosystems, increased flood damage, reduced water resources in southern Australia, more deaths and infrastructure damage during heatwaves, more fire-related impacts on ecosystems and settlements in southern Australia and across New Zealand, greater risk to coastal infrastructure and ecosystems, and reduced water availability in the Murray-Darling Basin and southern Australia (*high confidence*). Benefits are projected for some sectors and locations *(high confidence)*, including reduced winter mortality and energy demand for heating, increased forest growth, and enhanced pasture productivity. Adaptation is occurring and adaptation is becoming mainstreamed in some planning processes (*high confidence*). Adaptive capacity is considered generally high in many human systems, but adaptation implementation faces major barriers, especially for transformational responses (*high confidence*). Some synergies and trade-offs exist between different adaptation responses, and between mitigation and adaptation, with interactions occurring both within and outside the region (*very high confidence*).	(Reisinger et al., 2014)

Vulnerability remains uncertain due to incomplete consideration of socio-economic dimensions *(very high confidence),* including governance, institutions, patterns of wealth and aging, access to technology and information, labour force participation, and societal values.	
Emissions reductions under Nationally Determined Contributions from signatories to the Paris Agreement are consistent with a global warming of 2.5-3.0°C above pre-industrial temperatures by 2100. Much deeper emission reductions are needed prior to 2030 to limit warming to 1.5°C. There are limits to adaptation and adaptive capacity for some human and natural systems at global warming of 1.5°C, with associated losses. Climate impacts will disproportionately affect the welfare of impoverished and vulnerable people because they lack adaptation resources. Strengthening the climate-action capacities of national and sub-national authorities, civil society, the private sector, Indigenous people and local communities can support implementation of actions.	(IPCC, 2018)
Land-related responses that contribute to climate change adaptation and mitigation can also combat desertification, land degradation, and enhance food security. Appropriate design of policies, institutions and governance systems at all scales can contribute to land-related adaptation and mitigation while facilitating the pursuit of climate-adaptive development pathways. Mutually supportive climate and land policies have the potential to save resources, amplify social resilience, support ecological restoration, and foster collaboration between stakeholders. Near-term action to address climate change adaptation and mitigation, desertification, land degradation and food security can bring social, ecological, economic and development co-benefits. Delaying action (both mitigation and adaptation) will be more costly.	(IPCC, 2019a)
The rate of global mean sea-level rise of 3.6 mm per year for 2006–2015 is unprecedented over the last century. Extreme wave heights, coastal erosion and flooding, have increased in the Southern Ocean by around 1.0 cm per year over the period 1985–2018. Some species of plants and animals have increased in abundance, shifted their range, and established in new areas as glaciers receded and the snow-free season lengthened. Some cold-adapted or snow-dependent species have declined in abundance, increasing their risk of extinction, notably on mountain summits. Many marine species have shifted their range and seasonal activities. Altered interactions between species have caused cascading impacts on ecosystem structure and functioning. Mean sea-level rise projections are higher by 0.1 m compared to AR5 under RCP8.5 in 2100. Extreme sea-level events that are historically rare (once per century) are projected to occur frequently (at least once per year) at many locations by 2050. Projected ecosystem responses include losses of species habitat and diversity, and degradation of ecosystem functions. Warm water corals are at high risk already and are projected to transition to very high risk even if global warming is limited to 1.5°C. Governance arrangements (e.g., marine protected areas, spatial plans and water management systems) are too fragmented across administrative boundaries and sectors to provide integrated responses to the increasing and cascading risks. Financial, technological, institutional and other barriers exist for implementing responses. Enabling climate resilience and sustainable development depends critically on urgent and ambitious emissions reductions coupled with coordinated, sustained and increasingly ambitious adaptation actions. This includes better cooperation and coordination among governing authorities, education and climate literacy, sharing of information and knowledge, finance, addressing social vulnerability and equity, and institutional support.	(IPCC, 2019b)

11.1.2 Economic, Demographic and Social Trends

Economic, demographic and socio-cultural trends influence the exposure, vulnerability and adaptive capacity of individuals and communities (*high confidence*) (Elrick-Barr et al., 2016; Smith et al., 2016; Hayward, 2017; B. Frame et al., 2018; Plummer et al., 2018; Smith et al., 2018; Gartin et al., 2020). In the absence of proactive adaptation, climate change, impacts are projected to worsen inequalities between Indigenous and non-Indigenous people and other vulnerable groups (Green et al., 2009; Manning et al., 2014; Ambrey et al., 2017) (*high confidence*). Socio-economic inequality, low incomes and high levels of debt, poor health and disabilities increase vulnerability and limit adaptation (Hayward, 2012) (11.7.2). Lack of services, such as schools and medical services, in poorer and rural areas, and decision-making processes that privilege some voices over others, exacerbate inequalities (Kearns et al., 2009; Hinkson and Vincent, 2018).

Changes to the composition and location of different demographic groups in the region contributes to increased exposure or vulnerability to climate change (*medium confidence*). Australia's population reached 25 million in 2018 and is projected to grow to 37.4–49.2 million by 2066, with most growth in major cities (accounting for 81% of Australia's population growth from 2016–17) (ABS, 2018), although COVID-19 is expected to slow the growth rate (CoA, 2020c). Highest growth rates outside of major cities occurred mostly in coastal regions (ABS, 2017) which have built assets exposed to sea-level rise. New Zealand's population was 5.1 million at the end of 2020 and is projected to increase to 6.0–6.5 million by 2068 assuming no marked changes in migration patterns (Stats NZ, 2016; Stats NZ, 2021). Although the population densities of both countries are much lower than other OECD countries, they are highly urbanized with over 86% living in urban areas in both countries (Productivity Commission, 2017; World Bank, 2018). This proportion is projected to increase to over 90% by 2050 (UN DESA, 2019) mostly in coastal areas (Rouse et al., 2017). Consideration of climate change impacts when planning and managing such growth and associated infrastructure could help avoid new vulnerabilities being created, particularly from wildfires, sea-level rise, heat stress and flooding.

The region has an increasingly diverse population through the arrival of migrants, including those from the Pacific, whose innovations, skills and transnational networks enhance their and others' adaptive capacity (De et al., 2016; Fatorić et al., 2017; Barnett and McMichael, 2018), although language barriers and socio-economic disadvantage can create vulnerabilities for some (11.7.2).

Climate change inaction exacerbates intergenerational inequity including prospects for the current younger population (Hayward, 2012). Increasing transient worker populations (ABS, 2018) may diminish social networks and adaptive capacity (Jiang et al., 2017). The region has an aging population and increasing numbers of people living on their own who are highly vulnerable to extreme events, including heat stress and flooding (Zhang et al., 2013).

Socio-economic trends are affected by global mega trends (KPMG, 2021), which are expected to influence the region's ability to implement climate change adaptation strategies (World Economic Forum, 2014). Digital technological advances have potential benefits for building adaptive capacity (Deloitte, 2017a).

11.2 Observed and Projected Climate Change

11.2.1 Observed Climate Change

Regional climate change has continued since the Fifth Assessment Report (AR5) in 2014, with trends exacerbating many extreme events (*very high confidence*). The following changes are quantified with references in Tables 11.2a and 11.2b. The region has continued to warm (Figure 11.1), with more extremely high temperatures and fewer extremely low temperatures. Snow depths and glacier volumes have declined. Sea-level rise and ocean acidification have continued. Northern Australia has become wetter, while April-October rainfall has decreased in south-western and south-eastern Australia. In New Zealand, most of the south has become wetter while most of the north has become drier (Figure 11.2). The frequency, severity and duration of extreme fire weather conditions have increased in southern and eastern Australia and eastern New Zealand. Changes in extreme rainfall are mixed. There has been a decline in tropical cyclone frequency near Australia.

Reliable measurements are limited for some types of storms, particularly thunderstorms, lightning, tornadoes and hail (Walsh et al., 2016). Many high impact events are a combination of interacting physical processes across multiple spatial and temporal scales (e.g. fires, heatwaves and droughts), and better understanding of these extreme and compound events is needed (Zscheischler et al., 2018).

Some of the observed trends and events can be partly attributed to anthropogenic climate change, as documented in Chapter 16. Examples include regional warming trends and sea-level rise, terrestrial and marine heatwaves, declining rainfall and increasing fire weather in southern Australia, and extreme rainfall and severe droughts in New Zealand.

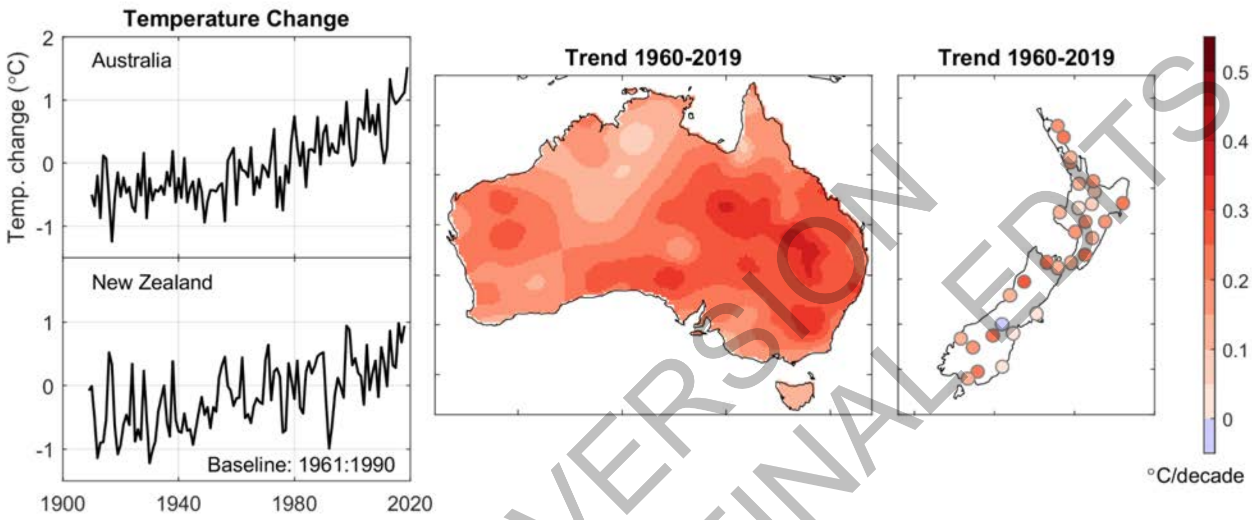

Figure 11.1: Observed temperature changes in Australia and New Zealand. Annual temperature change time-series are shown for 1910–2019. Mean annual temperature trend maps are shown for 1960–2019 using contours for Australia and individual sites for New Zealand. Data courtesy of BoM and NIWA.

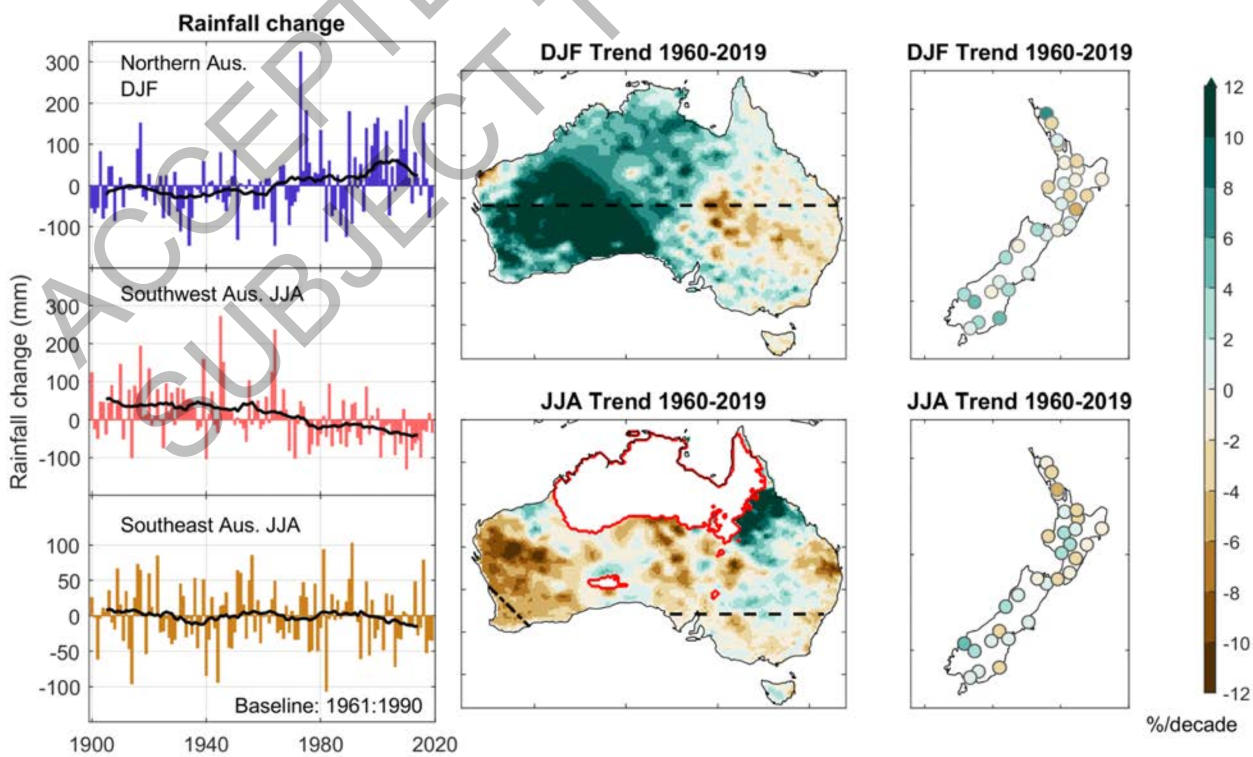

Figure 11.2: Observed rainfall changes in Australia and New Zealand. Rainfall change time-series for 1900–2019 are shown for northern Australia (December-February: DJF), southwest Australia (June-August: JJA) and southeast

Australia (JJA). Dashed lines on the maps for Australia show regions used for the time-series. Rainfall trend maps are shown for 1960–2019 (DJF and JJA) using contours for Australia and individual sites for New Zealand. Areas of low Australian rainfall (less than 0.25 mm/day) are shaded white in JJA. Data courtesy of BoM and NIWA.

Table 11.2a: Observed climate change for Australia**.**

Climate variable	Observed change	References
Air temperature over land	Increased by 1.4°C from 1910–2019. 2019 was the warmest year, and nine of the ten warmest on record occurred since 2005. Clear anthropogenic attribution.	(BoM, 2020b; BoM and CSIRO, 2020; Trewin et al., 2020; Gutiérrez et al., 2021)
Sea surface temperature	Increased by 1.0°C from 1900-2019 (0.09ºC/decade), with an increase of 0.16-0.20ºC/decade since 1950 in the south-east. Eight of the ten warmest years on record occurred since 2010.	(BoM and CSIRO, 2020)
Air temperature extremes over land	More extremely hot days and fewer extremely cold days in most regions. Weaker warming trends in minimum temperatures in southeast Australia compared to elsewhere during 1960-2016. Frost frequency in south-east and south-west Australia has been relatively unchanged since the 1980s. Very high monthly maximum or minimum temperatures that occurred around 2% of the time in the past (1960–1989) now occur 11-12% of the time (2005–2019). Multi-day heatwave events have increased in frequency and duration across many regions since 1950. In 2019, the national average maximum temperature exceeded the 99th percentile on 43 days (more than triple the number in any of the years prior to 2000) and exceeded 39°C on 33 days (more than the number observed from 1960 to 2018 combined).	(Perkins-Kirkpatrick et al., 2016; Alexander and Arblaster, 2017; Pepler et al., 2018; BoM and CSIRO, 2020; Perkins-Kirkpatrick and Lewis, 2020; Trancoso et al., 2020)
Sea temperature extremes	Intense marine heatwave in 2011 near Western Australia (peak intensity 4°C, duration 100 days) - likelihood of an event of this duration estimated to be about 5 times higher than under pre-industrial conditions. Marine heatwave over northern Australia in 2016 (peak intensity 1.5°C, duration 200 days). Marine heatwave in the Tasman Sea and around southeast mainland Australia and Tasmania from September 2015 to May 2016 (peak intensity 2.5°C, duration 250 days) - likelihood of an event of this intensity and duration has increased about 50-fold. Marine heatwave in the Tasman Sea from November 2017 to March 2018 (peak intensity 3°C, duration 100 days). Marine heatwave on the Great Barrier Reef in 2020 (peak intensity 1.2°C, duration 90 days) (BoM, 2020).	(BoM and CSIRO, 2018; BoM, 2020a; Laufkötter et al., 2020; Oliver et al., 2021)
Rainfall	Northern Australian rainfall has increased since the 1970s, with an attributable human influence. April to October rainfall has decreased 16% since the 1970s in south-western Australia (partly due to human influence) and 12% from 2000-2019 in south-eastern Australia. Australian-average rainfall was lowest on record in 2019.	(Delworth and Zeng, 2014; Knutson and Zeng, 2018; Dey et al., 2019; BoM, 2020c; BoM and CSIRO, 2020)
Rainfall extremes	Hourly extreme rainfall intensities increased by 10–20% in many locations between 1966–1989 and 1990–2013. Daily rainfall associated with thunderstorms increased 13-24% from 1979-2016, particularly in northern Australia. Daily rainfall intensity increased in the northwest from 1950–2005 and in the east from 1911–2014, and decreased in the south-west and Tasmania from 1911–2010.	(Donat et al., 2016; Alexander and Arblaster, 2017; Evans et al., 2017; Guerreiro et al., 2018; Dey et al., 2019; BoM and CSIRO, 2020; Bruyère et al., 2020; Dowdy, 2020; Dunn et al., 2020; Gutiérrez et al., 2021)

Drought	Major Australian droughts occurred in 1895-1902, 1914-1915, 1937-1945, 1965-1968, 1982-1983, 1997-2009 and 2017-2019. Fewer droughts have occurred across most of northern and central Australia since the 1970s, more droughts in the south-west since the 1970s, and mixed drought trends in the south-east since the late 1990s.	(Gallant et al., 2013; Delworth and Zeng, 2014; Alexander and Arblaster, 2017; Dai and Zhao, 2017; Knutson and Zeng, 2018; Dey et al., 2019; Spinoni et al., 2019; BoM, 2020b; Dunn et al., 2020; Rauniyar and Power, 2020; BoM, 2021; Seneviratne et al., 2021)
Windspeed	Windspeed decreased 0.067 m/s per decade over land from 1941-2016, with a decrease of 0.062 m/s per decade over land from 1979–2015, and a decrease of 0.05-0.10 m/s per decade over land from 1988-2019. Windspeed increased 0.02 m/s per year across the Southern Ocean from 1985-2018.	(Troccoli et al., 2012; Young and Ribal, 2019; Blunden and Arndt, 2020; Azorin-Molina et al., 2021)
Sea-level rise	Relative sea level rise was 3.4 mm/year from 1993-2019, which includes the influence of internal variability (e.g. ENSO) and anthropogenic greenhouse gases.	(Watson, 2020)
Fire	An increase in the number of extreme fire weather days from July 1950 to June 1985 compared to July 1985 to June 2020, especially in the south and east, partly attributed to climate change. More dangerous conditions for extreme pyro convection events since 1979, particularly in south-eastern Australia. Extreme fire weather in 2019-2020 was at least 30% more likely due to climate change.	(Dowdy and Pepler, 2018; BoM and CSIRO, 2020; van Oldenborgh et al., 2021)
Tropical cyclones and other storms	Fewer tropical cyclones since 1982, with a 22% reduction in translation speed over Australian land areas from 1949-2016. No significant trend in the number of East Coast Lows. From 1979–2016, thunderstorms and dry lightning decreased in spring and summer in northern and central Australia, decreased in the north in autumn, and increased in the south-east in all seasons. Convective rainfall intensity per thunderstorm increased by about 20% in the north and 10% in the south. An increase in the frequency of large to giant hail events across south-eastern Queensland and north-eastern and eastern New South Wales in the most recent decade. Seven major hail storms over eastern Australia from 2014-2020 and three major floods over eastern Australia from 2019-2021.	(Pepler et al., 2015b; Ji et al., 2018; Kossin, 2018; BoM and CSIRO, 2020; Dowdy, 2020; ICA, 2021) (Bruyère et al., 2020)
Snow	At Spencers Creek (1830 m elevation) in NSW, annual maximum snow depth decreased 10% and length of snow season decreased 5% during 2000–2013 relative to 1954–1999. At Rocky Valley Dam (1650 m elevation) in Victoria, annual maximum snow depth decreased 5.7 cm/decade from 1954-2011. At Mt Hotham, Mt Buller and Falls Creek (1638-1760 m elevation), annual maximum snow depth decreased 15%/decade from 1988-2013.	(Bhend et al., 2012; Fiddes et al., 2015; Pepler et al., 2015a; BoM and CSIRO, 2020)
Ocean acidification	Average pH of surface waters has decreased since the 1880s by about 0.1 (over 30% increase in acidity).	(BoM and CSIRO, 2020)

Table 11.2b: Observed climate change for New Zealand.

Climate variable	Observed change	References
Air temperature	Increased by 1.1°C from 1909–2019. Warmest year on record was 2016, followed by 2018 and 1998 as equal 2nd warmest.	(MfE, 2020a; NIWA, 2020)

	Six years between 2013 and 2020 were among New Zealand's warmest on record.	
Sea surface temperature	Increased by 0.2°C/decade from 1981–2018.	(MfE, 2020a)
Air temperature extremes	Number of frost days (below 0 degrees Celsius) decreased at 12 of 30 sites, the number of warm days (over 25°C) increased at 19 of 30 sites, and the number of heatwave days increased at 18 of 30 sites during 1972–2019. Increase in the frequency of hot February days exceeding the 90th percentile between 1980–1989 and 2010–2019, with some regions showing more than a five-fold increase.	(Harrington, 2020; MfE, 2020a)
Sea temperature extremes	The eastern Tasman Sea experienced a marine heatwave in 2017/18 lasting 138 days with a maximum intensity of 4.1°C, and another marine heatwave in 2018/19 lasting 137 days with a maximum intensity of 2.8°C.	(NIWA, 2019; Salinger et al., 2019b; Salinger et al., 2020; Oliver et al., 2021)
Rainfall	From 1960–2019, almost half of the 30 sites had an increase in annual rainfall (mostly in the south) and 10 sites (mostly in the north) had a decrease, but few of the trends are statistically significant. Rainfall increased by 2.8% per decade in Whanganui, 2.1% per decade in Milford Sound and 1.3% per decade in Hokitika. Rainfall decreased by 4.3% per decade in Whangarei and 3.2% per decade in Tauranga.	(MfE, 2020a)
Rainfall extremes	The number of days with extreme rainfall increased at 14 of 30 sites and decreased at 11 sites from 1960–2019. Most sites with increasing annual rainfall had more extreme rainfall and most sites with decreasing annual rainfall had less extreme rainfall.	(MfE, 2020a)
Drought	Drought frequency increased at 13 of 30 sites from 1972–2019 and decreased at 9 sites. Drought intensity increased at 14 sites, 11 of which are in the north, and decreased at 9 sites, 7 of which are in the south.	(MfE, 2020a)
Windspeed	Since 1970, the wind belt has often been shifted to the south of New Zealand, bringing an overall decrease in wind-speed over the country. For 1980–2019, the annual maximum wind gust decreased at 11 of the 14 sites that had enough data to calculate a trend, and increased at 2 of the 14 sites	(MfE, 2020a)
Sea-level rise	Increased 1.8 mm/year from 1900–2018 and 2.4 mm/year from 1961–2018, mostly due to climate change.	(Bell and Hannah, 2019)
Fire	Six of 28 sites (Napier, Lake Tekapo, Queenstown, Gisborne, Masterton, and Gore) had an increase in days with very high or extreme fire danger from 1997–2019 and 6 sites (Blenheim, Christchurch, Nelson, Tara Hills, Timaru, and Wellington) had a decrease. An increase in fire impacts from 1988–2018 included homes lost, damaged, threatened and evacuated.	(Pearce, 2018; MfE, 2020a)
Tropical cyclones and other storms	No significant change in storminess. Three major floods and two major hail-storms during 2019-2021.	(MfE, 2020a; ICNZ, 2021)

Snow and ice	From 1978-2019, the snowline rose 3.7 m/year. From 1977 to 2018, glacier ice volume decreased from 26.6 km^3 to 17.9 km^3 (a loss of 33%). From 1978-2016, the area of 14 glaciers in the Southern Alps declined 21%. The end-of-summer snowline elevation for 50 glaciers rose 300 m from 1949-2019. In the Southern Alps, extreme glacier mass loss was at least six times more likely in 2011, and ten times more likely in 2018, due to climate change.	(Baumann et al.; Salinger et al., 2019a; Chinn and Chinn, 2020; MfE, 2020a; Salinger et al., 2021) (Vargo et al., 2020)
Ocean acidification	Sub-Antarctic ocean off the Otago coast became 7% more acidic from 1998–2017.	(MfE, 2020a)

11.2.2 Projected Climate Change

There are three main sources of uncertainty in climate projections: emission scenarios, regional climate responses, and internal climate variability (CSIRO and BOM, 2015). Emission scenario uncertainty is captured in four Representative Concentration Pathways (RCPs) for greenhouse gases and aerosols. RCP2.6 represents low emissions, RCP4.5 medium emissions and RCP8.5 high emissions. Regional climate response uncertainty and internal climate variability uncertainty are captured in climate model simulations driven by the RCPs.

Further climate change is inevitable, with the rate and magnitude largely dependent on the emission pathway (IPCC, 2021) (*very high confidence*). Preliminary projections based on CMIP6 models are described in the IPCC Working Group I Atlas. For Australia, the CMIP6 projections broadly agree with CMIP5 projections except for a group of CMIP6 models with greater warming and a narrower range of summer rainfall change in the north and winter rainfall change in the south (Grose et al., 2020). For New Zealand, the CMIP6 projections are similar to CMIP5, but the CMIP6 models indicate greater warming, a smaller increase in summer precipitation and a larger increase in winter precipitation (Gutiérrez et al., 2021).

Dynamical and/or statistical downscaling offers the prospect of improved representation of regional climate features and extreme weather events (IPCC 2021: Working Group I Chapter 10), but the added value of downscaling is complex to evaluate (Ekström et al., 2015; Rummukainen, 2015; Virgilio et al., 2020). Downscaled simulations are available for New Zealand (MfE, 2018) and various Australian regions (Evans et al., 2020) (IPCC 2021: Working Group I Atlas). Further downscaling was recommended by the Royal Commission into National Natural Disaster Arrangements (CoA, 2020e). Projections for rainfall, thunderstorms, hail, lightning and tornadoes have large uncertainties (Walsh et al., 2016; MfE, 2018).

Future changes in climate variability are affected by the El Niño Southern Oscillation (ENSO), Southern Annular Mode (SAM), Indian Ocean Dipole (IOD) and Interdecadal Pacific Oscillation (IPO). An increase in strong El Niño and La Niña events is projected (Cai, 2015), along with more extreme positive phases of the IOD (Cai et al., 2018) and a positive trend in SAM (Lim et al., 2016), but potential changes in the IPO are unknown (NESP ESCC, 2020). There is uncertainty about regional climate responses to projected changes in ENSO (King et al., 2015; Perry et al., 2020; Virgilio et al., 2020).

Australian climate projections are quantified with references in Table 11.3a. Further warming is projected, with more hot days, fewer cold days, reduced snow cover, ongoing sea-level rise and ocean acidification (*very high confidence*). Winter and spring rainfall and soil moisture are projected to decrease with more droughts in southern Australia, increased extreme rainfall intensity, higher evaporation rates, decreased wind over southern mainland Australia, increased wind over Tasmania, and more extreme fire weather in southern and eastern Australia (*high confidence*). Increased winter rainfall is projected over Tasmania, with decreased rainfall in south-western Victoria in autumn and in western Tasmania in summer, fewer tropical cyclones with a greater proportion of severe cyclones and decreased soil moisture in the north (*medium confidence*). Hailstorm frequency may increase (*low confidence*).

New Zealand climate projections are quantified with references in Table 11.3b. Further warming is projected, with more hot days, fewer cold days, less snow and glacial ice, ongoing sea-level rise and ocean acidification (*very high confidence*). Increases in winter and spring rainfall are projected in the west of the North and South Islands, with drier conditions in the east and north, caused by stronger westerly winds (*medium confidence*). In summer, wetter conditions are projected in the east of both islands, with drier conditions in the west and central North Island (*medium confidence*). Fire weather is projected to increase in most areas, except for Taranaki-Manawatū, West Coast and Southland (*medium confidence*). Extreme rainfall is projected to increase over most regions, with increased extreme wind-speeds in eastern regions, especially in Marlborough and Canterbury, and reduced relative humidity almost everywhere, except for the West Coast in winter (*medium confidence*). Drought frequency may increase in the north (*medium confidence*).

Table 11.3a: Projected climate change for Australia. Projections are given for different Representative Concentration Pathways (RCP2.6 is low, RCP4.5 is medium, RCP8.5 is high) and years (e.g. 20–year period centered on 2090). Uncertainty ranges are generally 10–90th percentile, and median projections are given in square brackets where possible. The four Australian regions are shown in Chapter 2 of (CSIRO and BOM, 2015). Preliminary projections based on CMIP6 models are included for some climate variables from the IPCC (2021) Working Group 1 report.

Climate variable	Projected change (year, RCP) relative to 1986-2005	References
Air temperature	Annual mean temperature • +0.5–1.5°C (2050, RCP2.6), +1.5–2.5°C (2050, RCP8.5), +0.5–1.5°C (2090, RCP2.6), +2.5–5.0°C (2090, RCP8.5) • Weaker increase in the south, stronger increase in the centre. • Preliminary CMIP6 projections: +0.6-1.3ºC (2050, SSP1-RCP2.6), +1.2-2.0ºC (2050, SSP5-RCP8.5), +0.6-1.5ºC (2090, SSP1-RCP2.6), +2.8-4.9ºC (2090, SSP5-RCP8.5) relative to 1995-2014	(NESP ESCC, 2020; IPCC, 2021)
Sea surface temperature	• + 0.4–1.0°C (2030, RCP8.5), • +2–4°C (2090, RCP8.5).	(CSIRO and BOM, 2015)
Air temperature extremes	• Annual frequency of days over 35°C may increase 20–70% by 2030 (RCP4.5), and 25–85% (RCP2.6) to 80–350% (RCP8.5) by 2090 • Heatwaves may be 85% more frequent if global warming increases from 1.5 to 2.0°C, and four times more frequent for a 3°C warming • Annual frequency of frost days may decrease by 10–40% (2030, RCP4.5), 10–40% (2090, RCP2.6) and 50–100% (2090, RCP8.5).	(CSIRO and BOM, 2015; Trancoso et al., 2020)
Rainfall	Annual mean rainfall • South: –15 to +2% (2050, RCP2.6), –14 to +3% (2050, RCP8.5), –15 to +3% (2090, RCP2.6), –26 to +4% (2090, RCP8.5) • East: –13 to +7% (2050, RCP2.6), –17 to +8% (2050, RCP8.5), –19 to +6% (2090, RCP2.6), –25 to +12% (2090, RCP8.5) • North: –12 to +5% (2050, RCP2.6), -8 to +11% (2050, RCP8.5), -12 to +3% (2090, RCP2.6), -26 to +23% (2090, RCP8.5) • Rangelands: -18 to +3% (2050, RCP2.6), -15 to +8% (2050, RCP8.5), -21 to +3% (2090, RCP2.6), -32 to +18% (2090, RCP8.5).	(Liu et al., 2018; NESP ESCC, 2020)
Rainfall extremes	Intensity of daily-total rain with 20-year recurrence interval • +4 to +10% (2050, RCP2.6), • +8 to +20% (2050, RCP8.5), • +4 to +10% (2090, RCP2.6), • +15 to +35% (2090, RCP8.5).	(NESP ESCC, 2020)
Drought	Time in drought (Standardized Precipitation Index below -1) • Southern Australia: 32-46% [39%] (1995), 38-68% [54%] (2050, RCP8.5), 41-81% [60%] (2090, RCP8.5) • Eastern Australia: 25-46% [37%] (1995), 24-67% [47%] (2050, RCP8.5), 19-76% [56%] (2090, RCP8.5) • Northern Australia: 26-44% [34%] (1995), 18-54% [40%] (2050, RCP8.5), 9-81% [39%] (2090, RCP8.5)	(Kirono et al., 2020)

	• Australian Rangelands: 29-43% [34%] (1995), 26-58% [42%] (2050, RCP8.5), 23-70% [46%] (2090, RCP8.5).	
Windspeed	0-5% decrease over southern mainland Australia and 0-5% increase over Tasmania (2090, RCP8.5)	(CSIRO and BOM, 2015)
Sea-level rise	• South (Port Adelaide): 13-29 cm [21 cm] (2050, RCP2.6), 16-33 cm [25 cm] (2050, RCP8.5), 23-55 cm [39 cm] (2090, RCP2.6), 40-84 cm [61 cm] (2090, RCP8.5) • East (Newcastle): 14-30 cm [22 cm] (2050, RCP2.6), 19-36 cm [27 cm] (2050, RCP8.5), 22-54 cm [38 cm] (2090, RCP2.6), 46-88 cm [66 cm] (2090, RCP8.5) • North (Darwin City Council, 2011): 13-28 cm [21 cm] (2050, RCP2.6), 17-33 cm [25 cm] (2050, RCP8.5), 22-55 cm [38 cm] (2090, RCP2.6), 41-85 cm [62 cm] (2090, RCP8.5) • West (Port Hedland): 13-28 cm [20 cm] (2050, RCP2.6), 16-33 cm [24 cm] (2050, RCP8.5), 22-55 cm [38 cm] (2090, RCP2.6), 40-84 cm [61 cm] (2090, RCP8.5). These projections have not been updated to include an Antarctic dynamic ice sheet factor which increased global sea level projections for RCP8.5 by ~10 cm. Preliminary CMIP6 projections indicate +40-50 cm (2090, SSP1-RCP2.6) and +70-90 cm (2090, SSP5-RCP8.5).	(McInnes et al., 2015; Zhang et al., 2017; IPCC, 2019b) (IPCC, 2021)
Sea-level extremes	Increase in the allowance for a storm tide event with 1% annual exceedance probability (100-year return period) • South (Port Adelaide): 21 cm (2050, RCP2.6), 25 cm (2050, RCP8.5), 41 cm (2090, RCP2.6), 66 cm (2090, RCP8.5) • East (Newcastle): 24 cm (2050, RCP2.6), 30 cm (2050, RCP8.5), 49 cm (2090, RCP2.6), 86 cm (2090, RCP8.5) • North (Darwin): 21 cm (2050, RCP2.6), 26 cm (2050, RCP8.5), 43 cm (2090, RCP2.6), 71 cm (2090, RCP8.5) • West (Port Hedland): 21 cm (2050, RCP2.6), 26 cm (2050, RCP8.5), 43 cm (2090, RCP2.6), 70 cm (2090, RCP8.5).	(McInnes et al., 2015)
Fire	• East: annual number of severe fire weather days 0 to +30% (2050, RCP2.6), 0 to +60% (2050, RCP8.5), 0 to +30% (2090, RCP2.6), 0 to +110% (2090, RCP8.5) • Elsewhere: number of severe fire weather days +5 to +35% (2050, RCP2.6), +10 to +70% (2050, RCP8.5), +5 to +35% (2090, RCP2.6) +20 to +130% (2090, RCP8.5).	(Clarke and Evans, 2019; Dowdy et al., 2019, {Clark, 2021 #2658; Virgilio et al., 2019; NESP ESCC, 2020)
Tropical cyclones and other storms	• Eastern region tropical cyclones: -8 to +1% (2050, RCP2.6), -15 to +2% (2050, RCP8.5), -8 to +1% (2090, RCP2.6), -25 to +5% (2090, RCP8.5) • Western region tropical cyclones: -10 to -2% (2050, RCP2.6), -20 to -4% (2050, RCP8.5), -10 to -2% (2090, RCP2.6), -30 to -10% (2090, RCP8.5) • East coast lows: -15 to -5% (2050, RCP2.6), -30 to -10% (2050, RCP8.5), -15 to -5% (2090, RCP2.6), -50 to -20% (2090, RCP8.5). • Hailstorm frequency may increase, but there are large uncertainties.	(NESP ESCC, 2020; Raupach et al., 2021)

Snow and ice	• Maximum snow depth at Falls Creek and Mt Hotham may decline 30–70% (2050, B1) and 45–90% (2050, A1FI) relative to 1990. • Maximum snow depth at Mt Buller and Mt Buffalo may decline 40–80% (2050, B1) and 50–100% (2050, A1FI) relative to 1990. • Length of Victorian ski-season may contract 65–90% and mean annual snowfall may decline 60–85% (2070–2099, RCP8.5) relative to 2000–2010. • The snowpack may decrease by about 15% (2030, A2) to 60% (2070, A2).	(Bhend et al., 2012; Harris et al., 2016; Di Luca et al., 2018)
Ocean acidification	pH is projected to drop by about 0.1 (2090, RCP2.6) to 0.3 (2090, RCP8.5).	(CSIRO and BOM, 2015; Hurd et al., 2018)

Table 11.3b: Projected climate change for New Zealand. Projections are given for different Representative Concentration Pathways (RCP2.6 is low, RCP4.5 is medium, RCP8.5 is high) and years (e.g. 20–year period centered on 2090). Uncertainty ranges are 5–95th percentile, and median projections are given in square brackets where possible. Preliminary projections (10-90th percentile) based on CMIP6 models are included for some climate variables from the IPCC (2021) Working Group 1 report.

Climate variable	Projected change (year, RCP) relative to 1986-2005	References
Air temperature	Annual mean temperature • +0.2–1.3°C [0.7°C] (2040, RCP2.6), +0.5–1.7°C [1.0°C] (2040, RCP8.5), +0.1–1.4°C [0.7°C] (2090, RCP2.6), +2.0–4.6°C [3.0°C] (2090, RCP8.5) • More warming in summer and autumn, less in winter and spring. • More warming in the north than the south. • Preliminary CMIP6 projections: +0.4-1.1°C (2050, SSP1-RCP2.6), +0.9-1.7°C (2050, SSP5-RCP8.5), +0.5-1.5°C (2090, SSP1-RCP2.6), +2.2-4.1°C (2090, SSP5-RCP8.5) relative to 1995-2014	(MfE, 2018) (IPCC, 2021)
Sea surface temperature	• +1.0°C (2045, RCP8.5), • +2.5°C (2090, RCP8.5).	(Law et al., 2018b)
Air temperature extremes	• Annual frequency of days over 25°C may increase 20–60% (2040, RCP2.6) to 50–100% (2040, RCP8.5), and 20–60% (2090, RCP2.6) to 130–350% (2090, RCP8.5) • Annual frost frequency may decrease 20–60% (2040, RCP2.6) to 30–70% (2040, RCP8.5), and 20–60% (2090, RCP2.6) to 70–95% (2090, RCP8.5).	(MfE, 2018)

Rainfall	Annual mean rainfall • Waikato, Auckland and Northland: -7 to +7% (2040, RCP2.6), -8 to +5% (2040, RCP8.5), -5 to +11% [+2%] (2090, RCP2.6), -15 to +12% [-2%] (2090, RCP8.5) • Hawke's Bay and Gisborne: -8 to +8% [-1%] (2040, RCP2.6), -12 to +7% [-2%] (2040, RCP8.5), -9 to +4% [-2%] (2090, RCP2.6), -15 to +15% [-3%] (2090, RCP8.5) • Taranaki, Manawatū and Wellington: -4 to +9% [+1%] (2040, RCP2.6), -6 to +10% [+1%] (2040, RCP8.5), -6 to +15% [+3%] (2090, RCP2.6), -14 to +14% [+2%] (2090, RCP8.5) • Tasman-Nelson and Marlborough: -3 to +5% [+1%] (2040, RCP2.6), -3 to +8% [+1%] (2040, RCP8.5), -4 to +8% [+2%] (2090, RCP2.6), -3 to +15% [+5%] (2090, RCP8.5) • West Coast and Southland: -4 to +12% [+3%] (2040, RCP2.6), -4 to +12% [+4%] (2040, RCP8.5), -2 to +18% [+5%] (2090, RCP2.6), -8 to +23% (2090, RCP8.5) • Canterbury and Otago: -7 to +15% [+3%] (2040, RCP2.6), -7 to +19% [+3%] (2040, RCP8.5), -6 to +18% (2090, RCP2.6), -9 to +28% [+8%] (2090, RCP8.5).	(Liu et al., 2018; MfE, 2018)
Rainfall extremes	Intensity of daily rain with 20-year recurrence interval • +2.8 to 7.2% [5%] (2040, RCP2.6) • +4.2 to 10.4% [7%] (2040, RCP8.5) • +2.8 to 7.2% [5%] (2090, RCP2.6) • +12.6 to 31.5% [2%] (2090, RCP8.5).	(MfE, 2018)
Drought	Increase in potential evapotranspiration deficit • Northern and eastern North Island: 100-200 mm (2090, RCP8.5) • Western North Island: 50-100 mm (2090, RCP8.5) • Eastern South Island: 50-200 mm (2090, RCP8.5) • Western South Island: 0-50 mm (2090, RCP8.5).	(MfE, 2018)
Windspeed	99th percentile of daily mean wind speed • Northern North Island: 0 to -5% (2090, RCP8.5) • Southern North Island: 0 to +5% (2090, RCP8.5) • South Island: 0 to +10% (2090, RCP8.5).	(MfE, 2018)
Sea-level rise	• 23 cm (2050, RCP2.6) • 28 cm (2050, RCP8.5) • 42 cm (2090 RCP2.6) • 67 cm (2090 RCP8.5). These projections have not been updated to include an Antarctic dynamic ice sheet factor which increased global sea-level projections for RCP 8.5 by ~10 cm. Preliminary CMIP6 projections indicate 40-50 cm (2090, SSP1-RCP2.6) and 70-90 cm (2090, SSP5-RCP8.5).	(MfE, 2017a; IPCC, 2019b)
Sea-level extremes	For a rise in sea level of 30 cm, the 1-in-100-year high water levels may occur about: • Every 4 years at the port of Auckland • Every 2 years at the port of Dunedin • Once a year at the port of Wellington • Once a year at the port of Christchurch.	(PCE, 2015)

Fire	• Seasonal Severity Rating (SSR) increases 50-100% in coastal Marlborough and Otago, 40-50% in Wellington and 30-40% in Taranaki and Whanganui, 0-30% elsewhere (2050, A1B). • Number of days with very high or extreme fire weather increase >100% in coastal Otago, Marlborough and the lower North Island, 50-100% in Taupō and Rotorua, 20-50% in the rest of the North Island, and little change in the rest of the South Island (2050, A1B).	(Pearce et al., 2011)
Tropical cyclones and other storms	Poleward shift of mid-latitude cyclones and potential for a small reduction in frequency.	(MfE, 2018)
Snow and ice	• Maximum snow depth on 31 August may decline by 0-10% (2040, A1B) and 26-54% (2090, A1B). • Annual snow days may be reduced by 5-15 days (2040, RCP2.6), 10-25 days (2040, RCP8.5), 5-15 days (2090, RCP2.6) and 15-45 days (2090 RCP8.5). • Relative to 2015, New Zealand glaciers are projected to lose 36%, 53% and 77 % of their mass by the end of the century under RCP2.6, RCP4.5 and RCP8.5, respectively. • Over the period 2006-2099, New Zealand glaciers are projected to lose 50 to 92% of their ice volume for RCP2.6 to RCP8.5.	(Hendrikx et al., 2013; MfE, 2018; Marzeion et al., 2020) (Anderson et al. 2021)
Ocean acidification	pH is projected to drop by about 0.1 (2090, RCP2.6) to 0.3 (2090 RCP8.5).	(CSIRO and BOM, 2015; Hurd et al., 2018; Law et al., 2018b)

11.3 Observed Impacts, Projected Impacts and Adaptation

This section assesses observed impacts, projected risks, and adaptation for 10 sectors and systems. Boxes provide more detail on specific issues. Risk is considered in terms of vulnerability, hazards (impact driver), exposure, reasons for concern, complex and cascading risks (Chapter 1 Figure 1.2).

11.3.1 Terrestrial and Freshwater Ecosystems

11.3.1.1 Observed Impacts

Widespread and severe impacts on ecosystems and species are now evident across the region (*very high confidence*) (Table 11.4). Climate impacts reflect both on-going change and discrete extreme weather events (Harris et al., 2018) and the climatic change signal is emerging despite confounding influences (Hoffmann et al., 2019). Fundamental shifts are observed in the structure and composition of some ecosystems and associated services (Table 11.4). Impacts documented for species include global and local extinctions, severe regional population declines, and phenotypic responses (Table 11.4). In terrestrial and freshwater ecosystems, land use impacts are interacting with climate, resulting in significant changes to ecosystem structure, composition and function (Bergstrom et al., 2021) with some landscapes experiencing catastrophic impacts (Table 11.4). Some of observed changes may be irreversible where projected impacts on ecosystems and species persist (Table 11.5). Of note is the global extinction of an endemic mammal species, the Bramble Cay melomys (*Melomys rubicola*), from the loss of habitat attributable in part to sea-level rise and storm surges in the Torres Strait (Table 11.4).

Natural forest and woodland ecosystem processes are experiencing differing impacts and responses depending on the climate zone (*high confidence*). In Australia, an overall increase in the forest fire danger index, associated with warming and drying trends (Table 11.2a), has been observed particularly for southern and eastern Australia in recent decades (Box 11.1). The 2019-2020 mega wildfires of south eastern Australia burnt between 5.8 - 8.1 million hectares of mainly temperate broadleaf forest and woodland, but with substantial areas of rainforest also impacted, and were unprecedented in their geographic location, spatial extent, and forest types burnt (Boer et al., 2020; Nolan et al., 2020; Abram et al., 2021; Collins et al., 2021; Godfree et al., 2021). The human influence on these events is evident (Abram et al., 2021; van Oldenborgh et al., 2021) (Box 11.1). The fires had significant consequences for wildlife (Hyman et al., 2020; Nolan et al., 2020; Ward et al., 2020) (Box 11.1) and flow-on impacts for aquatic fauna (Silva et al., 2020). In southern Australia, deeply rooted native tree species can access soil and ground-water resources during drought, providing a level of natural resilience (Bell and Nikolaus Callow, 2020; Liu et al., 2020). However, the Northern Jarrah forests of south western Australia have experienced tree mortality and dieback from long term precipitation decline and acute heatwave-compounded drought (Wardell-Johnson et al., 2015; Matusick et al., 2018). While there is limited information on observed impacts for New Zealand, increased mast seeding events in beech forest ecosystems that stimulate invasive population irruptions have been recorded (Schauber et al., 2002; Tompkins et al., 2013).

Table 11.4: Observed impacts on terrestrial and freshwater ecosystems and species in the region where there is documented evidence that these are directly (e.g. a species thermal tolerances are exceeded) or indirectly (e.g. through changed fire regimes) the result of climate change pressures.

Ecosystem	Climate-related Pressure	Impact	Source
Australia			
Forest and woodlands of southern and southwestern Australia	30-year declining rainfall	Drought-induced canopy dieback across a range of forest and woodland types (e.g. northern jarrah)	(Matusick et al., 2018; Hoffmann et al., 2019)
	Multiple wildfires in short succession resulting from increased fire risk conditions including declining winter rainfall and increasing hot days	Local extirpations and replacement of dominant canopy tree species and replacement by woody shrubs due to seeders having insufficient time to reach reproductive age (Alpine Ash) or vegetative regeneration capacity is exhausted (Snow Gum woodlands)	(Slatyer, 2010; Bowman et al., 2014; Fairman et al., 2016; Harris et al., 2018; Zylstra, 2018)
	Background warming and drying created soil and vegetation conditions that are conducive to fires being ignited by lightning storms in regions that have rarely experienced fire over the last few millennia	Death of fire sensitive trees species from unprecedented fire events (Palaeo-endemic pencil pine forest growing in sphagnum, Tasmania, killed by lightning-ignited fires in 2016)	(Hoffmann et al., 2019)
Australia Alps Bioregion and Tasmanian alpine zones	Severe winter drought; warming and climate-induced biotic interactions	Shifts in dominant vegetation with a decline in grasses and other graminoids and an increase in forb and shrub cover in Bogong High Plains, Victoria, Australia	(Bhend et al., 2012; Hoffmann et al., 2019)

	Snow loss, fire, drought and temperature changes	Changing interactions within and among three key alpine taxa related to food supply and vegetation habitat resources: The mountain pygmy-possum (Burramys parvus), the mountain plum pine (Podocarpus lawrencei) and the bogong moth (Agrostis infusia)	(Hoffmann et al., 2019)
	Retreat of snow line	Increased species diversity in alpine zone	(Slatyer, 2010)
	Reduced snow cover	Loss of snow-related habitat for alpine zone endemic and obligate species	(ACE CRC, 2010; Pepler et al., 2015a; Thompson, 2016; Mitchell et al., 2019)
Wet Tropics World Heritage Area	Warming and increasing length of dry season	Some vertebrate species have already declined in both distribution area and population size, both earlier and more severely than originally predicted	(Moran et al., 2014; Hoffmann et al., 2019)
Sub-Antarctic Macquarie island	Reduced summer water availability for 17 consecutive summers, and increases in mean wind speed, sunshine hours and evapotranspiration over four decades	Dieback in the critically endangered habitat-forming cushion plant Azorella macquariensis in the fellfield and herb field communities	(Bergstrom et al., 2015; Hoffmann et al., 2019)
Mass mortality of wildlife species (flying foxes, freshwater fish)	Extreme heat events; rising water temperatures, temperature fluctuations, altered rainfall regimes including droughts and reduced in-flows	flying foxes - thermal tolerances of species exceeded; fish - amplified extreme temperature fluctuations, increasing annual water basin temperatures, extreme droughts and reduced runoff after rainfall	(AAS, 2019; Ratnayake et al., 2019; Vertessy et al., 2019)
Bramble Cay melomys (mammal) *Melomys rubicola*	Sea-level rise and storm surges in Torres Strait	Loss of habitat and global extinction	(Lunney et al., 2014; Gynther et al., 2016; Waller et al., 2017; CSIRO, 2018)
Koala, *Phascolarctos cinereus*	Increasing drought and rising temperatures, compounding impacts of habitat loss, fire and increasing human population	Population declines and enhanced risk of local extinctions	(Lunney et al., 2014)
Tawny dragon lizard, *Ctenophorus decresii*	Desiccation stress driven by higher body temperatures and declining rainfall	Population decline and potential local extinction in Flinders Ranges, South Australia	(Walker et al., 2015)

Birds	Changing thermal regimes including increasing thermal stress and changes in plant productivity are identified causal	Changes in body size, mass and condition and other traits linked to heat exchange	(Gardner et al., 2014a; Gardner et al., 2014b; Campbell-Tennant et al., 2015; Gardner et al., 2018; Hoffmann et al., 2019)
New Zealand			
Forest Birds	Warming	Increasing invasive predation pressure on endemic forest birds surviving in cool forest refugia, particularly larger-bodied bird species that nest in tree cavities and are poor dispersers	(Walker et al., 2019)
Coastal ecosystems	More severe storms and rising sea levels	Erosion of coastal habitats including dunes and cliffs is reducing habitat	(Rouse et al., 2017)
Beech forest ecosystems	Increasing mean temperatures and indirectly through effects of events like El Niño–Southern Oscillation (ENSO)	Increased beech mast seeding events that stimulate population irruptions for invasive rodents and mustelids which then prey on native species	(Schauber et al., 2002; Tompkins et al., 2013)

11.3.1.2 Projected Impacts

In the near-term (2030-2060), climate change is projected to become an increasingly dominant stress on the region's biodiversity, with some ecosystems experiencing irreversible changes in composition and structure and some threatened species becoming extinct (*high confidence*). Climate change will interact with current ecological conditions, threats and pressures, with cascading ecological impacts, including population declines, heat-related mortalities, extinctions and disruptions for many species and ecosystems (*high confidence*) (Table 11.5)**.** These include inadequate allocation of environmental flows for freshwater fish (Vertessy et al., 2019), native forest logging for old-growth forest-dependent fauna (Lindenmayer et al., 2015; Lindenmayer and Taylor, 2020a; Lindenmayer and Taylor, 2020b), and invasive species (Scott et al., 2018). Climate change has synergistic and compounding impacts particularly in bioregions already experiencing ecosystem degradation, threatened endemics, collapse of keystone species, including those of value to Indigenous Peoples, and high extinction rates as a consequence of human activities (Table 11.4) (Gordon, 2009; Australia SoE, 2016; Weeks et al., 2016; Cresswell and Murphy, 2017; Hare et al., 2019; MfE, 2019; Lindenmayer and Taylor, 2020a; Lindenmayer and Taylor, 2020b; Bergstrom et al., 2021). Some native species are projected to have potentially greater geographic range if they can colonise new areas, while other species may be resilient to projected climate change impacts (Bulgarella et al., 2014; K. Lawrence et al., 2017; Conroy et al., 2019; Rizvanovic et al., 2019).

In southern Australia, some forest ecosystems (alpine ash, snowgum woodland, pencil pine, northern jarrah) are projected to transition to a new state or collapse due to hotter and drier conditions with more fires (Table 11.5) (*high confidence*). In Australia, most native Eucalyptus forest plants have a range of traits that enable them to persist with recurrent fire through recovery buds (sprouters) or regenerate through seeding (Collins, 2020), affording them a high level of resilience. For high end projected 2060-2080 fire weather conditions in south east Australia (Clarke and Evans, 2019), stand-killing wildfires could occur at a severity and frequency greater than the regenerative capacity of seeders (Enright et al., 2015; Clarke and Evans, 2019). Most New

Zealand native plants are not fire resistant and are projected to be replaced by fire-resistant introduced species following climate-change related fires (Perry et al., 2014).

A loss of alpine biodiversity in the south-east Australian Alps Bioregion is projected in the near-term due to less snow on snow patch Feldmark and short alpine herb-fields as well as increased stress on snow-dependent plant and animal species (*high confidence*) (Table 11.3, Table 11.5). In Australia, invasive plants and weeds response rates are expected to be faster than for native species, and climate change could foster the appearance of a new set of weed species, with many bioregions facing increased impacts from non-native plants (*medium confidence)* (Gallagher et al., 2013; Scott et al., 2014; March-Salas and Pertierra, 2020) (Table 11.5), along with declines in some listed weeds (Duursma et al., 2013; Gallagher et al., 2013). In New Zealand, climate change is projected to enable invasive species to expand to higher elevations and southwards (Giejsztowt et al., 2020; MfE, 2020a) (Table 11.5) (*medium confidence*).

Projected responses of ecosystem processes are uncertain in part due to complex interactions of climate change with soil respiration, plant nutrient availability (Hasegawa et al., 2015; Orwin et al., 2015; Ochoa-Hueso et al., 2017) and changing fire regimes (Scheiter et al., 2015; Dowdy et al., 2019) (Table 11.5). For aquatic biota, responses will reflect seasonal differences in water temperature (Wallace et al., 2015), and changes in rainfall intensity, productivity and biodiversity (Jardine et al., 2015). Extreme floods may impact negatively on New Zealand river biota by mobilising nutrients, sediments and toxic chemicals, and aiding dispersal of invasive species. These effects are compounded by homogenisation of rivers through channelization (Death et al., 2015).

Improved coastal modelling, experiments and *in situ* studies are reducing uncertainties at a local scale about the impact of future sea-level rise on coastal freshwater terrestrial wetlands *(medium confidence)* (Shoo et al., 2014; Bayliss et al., 2018; Grieger et al., 2019). Low-lying coastal wetlands are susceptible to saltwater intrusion from sea-level rise (Shoo et al., 2014; Kettles and Bell, 2015; Finlayson et al., 2017) with consequences for species dependent on freshwater habitats (Houston et al., 2020). Saline habitat conditions will move inland and new coastal ecosystem states may emerge, including the World Heritage listed Kakadu's freshwater wetland (Bayliss et al., 2018) (Table 11.5). Increasingly, sea-level rise will shrink the intertidal zone, having implications for wading birds which use this zone (Tait and Pearce, 2019) (Box 11.6). The ecology of freshwater wetlands in New Zealand are projected to be impacted by the intersection of warming, drought and heavy rainfall (Pingram et al., 2021) (Table 11.5).

The impacts on species from projected global warming depend on their physiological and ecological responses for which knowledge is limited (Table 11.5) (Bulgarella et al., 2014; Carter et al., 2018; Green et al., 2021). Knowledge of projected impacts is constrained by uncertainties about the influence of physiological limits, barriers to dispersal, competition, the availability of habitat resources (Worth et al., 2014) and disruptions to ecological interactions (Lakeman-Fraser and Ewers, 2013; Parida et al., 2015; Porfirio et al., 2016). Gaps in ecological modelling of future climate impacts include consideration of long term rainfall and temperature changes (Grimm-Seyfarth et al., 2017; Grimm-Seyfarth et al., 2018), species dispersal rates, evolutionary capacity and phenotypic plasticity and the thresholds at which they are considered adequate to counter the impacts of climate change (Ofori et al., 2017b), as well as indirect effects including sea-level rise and altered fire regimes (Shoo et al., 2014; Cadenhead et al., 2016; He et al., 2016).

Table 11.5: An indicative selection of projected climate-change impacts on terrestrial and freshwater ecosystems and species in Australia and New Zealand respectively.

Ecosystem, species	Climate-related pressure	Projected Impact	Source
Australia			

Floristic composition of vegetation communities	Increases in temperature and reductions in annual precipitation by 2070. Many plant species based on median projection from five global climate models (ACCESS1.0, CNRM-CM5, HADGEM2-CC, MIROC5, NorESM1-M) centred on the decade 2070 under RCP8.5.	47% of vegetation types have characteristic plant species at risk of their climatic tolerances being exceeded from increasing mean annual temperature by 2070 with only 2% at risk from reductions in annual precipitation by 2070	(Gallagher et al., 2019)
Some south east Australian temperate forests	Reduction in winter rainfall and rising spring temperatures resulting in an increase in the frequency of very high fire weather conditions and increased risk of catastrophic wildfires; based on output from 15 CMIP5 GCMs using RCP 8.5 for years for 2060–2079 as compared to 1990–2009	Increase in fire frequency prevents recruitment of obligate seeder resulting in changing dominant species and vegetation structure including long lasting or irreversible shift in formation from tall wet temperate eucalypt forests dominated by obligate seeder trees (e.g. Alpine Ash) to open forest or in worst case to shrubland.	(Doherty et al., 2017; Zylstra, 2018; Bowman et al., 2019; Dowdy et al., 2019; Naccarella et al., 2020)
		Declining rainfall and regolith drying, more unplanned, intense fires and declining productivity places stress on tree growth and compromises biodiversity in northern jarrah forest.	(Wardell-Johnson et al., 2015)
		Tree line stasis or regression (Snow Gum)	(Doherty et al., 2017) (Bowman et al., 2019; Naccarella et al., 2020)
	Increase in lightning-ignited landscape fires along with contracting palaeoendemic refugia due to warmer and drier climates	Population collapse and severe range contraction of slow-growing, fire-sensitive palaeoendemic temperate rainforest species (e.g. Pencil Pine)	(Doherty et al., 2017) (Bowman et al., 2019)
	Rhizosphere responses or accelerated rates of soil organic matter decomposition	Plant nutrient availability may be enhanced	(Hasegawa et al., 2015; Ochoa-Hueso et al., 2017)
Alpine ecosystems	Increasing global warming and rising temperatures ongoing reduction in snow cover and winter rain, and increasing frequency and magnitude of wildfires	Loss of alpine vegetation communities (snow patch Feldmark and short alpine herb-fields) and increased stress on snow-dependent plant and animal species; changing suitability for invasive species	(Slatyer, 2010; Morrison and Pickering, 2013; Pepler et al., 2015a; Williams et al., 2015; Harris et al., 2017)
Northern tropical savannahs	Rainfall and CO_2 effects	Potentially resulting in an in increase in ecosystem carbon storage	(Scheiter et al., 2015)
Murray-Darling River Basin	Drought	Reduced river flow; mass fish kills	(Grafton et al., 2014; AAS, 2019)
Unimpaired river basins	Elevated CO_2 levels	Increase plant water use reduces stream flow	(Ukkola et al., 2016)

Bearded dragons (lizards), *Pogona spp.*	Changes in precipitation	P. henrylawsoni and P. microlepidota to gain suitable habitat, P. nullarbor and P. vitticeps showing the most potential loss	(Wilson and Swan, 2017; Silva et al., 2018)
Xeric bees	Broad temperate tolerances, arid climate adapted	Climate resilient, only small response	(Silva et al., 2018)
Great desert skink Liopholis kintorei	Buffering capacity of underground microclimates, for nocturnal and crepuscular ectotherms	Warming impacts projected to be indirect	(Moore et al., 2018)
22 narrow range fish species in imminent risk of extinction	Projected changes in rainfall, run-off, air temperatures and the frequency of extreme events (drought, fire, flood) compound risk from other key threats especially invasive species	Extinction likely within next 20 years	(Lintermans et al., 2020)
Freshwater taxa (freshwater fish, crayfish, turtles and frogs)	Changed hydrological regimes	Substantial changes to the composition of faunal assemblages in Australian rivers well before the end of this century, with gains/losses balanced for fish but suitable habitat area predicted to decrease for many crayfish and turtle species and nearly all frog species	(James et al., 2017)
New Zealand			
Modified lowland wetlands	Intersection of warming, drought and heavy rainfall (ex-tropical cyclones)	Prolonged anoxic conditions in waterways (blackwater events) leading to mortality of fish (e.g. shortfin eels) and invertebrates, while botulism outbreaks can lead to impacts on waterfowl	(Pingram et al., 2021)
Native forests and lands	Elevated CO_2 levels, warming, increased precipitation.	Short-term beneficial effects on carbon storage. Droughts in eastern areas would decrease productivity and rates of carbon storage in the medium term	(Ausseil et al., 2019b)
	Increased fire intensity and frequency in hot and dry parts of New Zealand	Much of the native vegetation has no fire adaptations causing vulnerability to local extinction due to 'interval squeeze'	(Perry et al., 2014)
Freshwater rivers	Rainfall variation	Cascading effects of warming, drought, floods, and algal blooms compounded by water abstraction	(Macinnis-Ng et al., 2021)
Three species of naturalized woody weeds	Warming and increased CO_2 levels	Increased geographic range	(Sheppard and Stanley, 2014)

Kauri tree, *Agathis australis*	Lower than average rainfall stimulates a drought-deciduous response in this evergreen species	Increased litter fall	(Macinnis-Ng and Schwendenmann, 2015)
Windmill palm	Warming	Increased geographic range	(Aguilar et al., 2017)
New Zealand tussock grasslands	Warming	Enhanced respiration	(Graham et al., 2014)
Invasive species	Warming	Increased invasive species abundance & increased predation on native species	(Tompkins et al., 2013; Macinnis-Ng et al., 2021)
	Warming	Expanded ranges of invasive species in higher/cooler areas	(Sheppard and Stanley, 2014; Walker et al., 2019)
	Warming	Change in flowering phenology and pollination competition	(Giejsztowt et al., 2020)
	Warming	Increase in invasive plants, insects, and pathogens from subtropical/tropical climates	(Macinnis-Ng et al., 2021)
Tuatara (reptile), *Sphenodon punctatus*	Warming	Temperature-dependent sex determination with more males hatch threatening small isolated populations	(Grayson et al., 2014)
	Warming	Increased geographic range	(Carter et al., 2018)
Cattle tick	Warming	Increased geographic range and risk of tick-spread anaemia in cattle	(K. Lawrence et al., 2017)
Brown mudfish, *Neochanna apoda*	Drought	Reduced flow regimes associated with drought interact with reduced habitat due to land use change, leading to population declines and potential local extinction	(White et al., 2016b; White et al., 2017)
Suter's skink (lizard) *Oligosoma suteri*	Warming	Increased suitable range but unclear if dispersal is possible because habitats are isolated	(Stenhouse et al., 2018)
Threatened endemic passerine bird, *Notiomystis cincta*	Fluctuations in total precipitation, particularly increased and more variable rainfall	Heavy rainfall can flood nests and kill fledglings while droughts can cause population-wide reproductive failure	(Correia et al., 2015)
Feral cats	Warming	Increased geographic range	(Aguilar et al., 2015b)

11.3.1.3 Adaptation

Managing climate change risks to ecosystems is primarily based on reducing the impact of other anthropogenic pressures, including invasive species, and facilitating natural adaptation (*high confidence*). This approach is most feasible within protected areas on public, private and Indigenous land and sea (Bellard et al., 2014; Liu et al., 2020) but is also applicable elsewhere (Barnes et al., 2015). Effective strategies promote ecosystem resilience through changing unsustainable land uses and management practices, increasing habitat connectivity, controlling introduced species, restoring habitats, implementing appropriate fire management, integrated risk assessment and adaptation planning (B. Frame et al., 2018; Lindenmayer et al., 2020; Macinnis-Ng et al., 2021). Complementary approaches include *ex situ* seed banks (Morrison and Pickering, 2013; Christie et al., 2020).

Best practice conservation adaptation planning is informed by data on key habitats, including refugia, and restoration that facilitates species movements and employs adaptive pathways (*very high confidence*) (Guerin and Lowe, 2013; Reside et al., 2014; Shoo et al., 2014; Keppel et al., 2015; Andrew and Warrener, 2017; Baumgartner et al., 2018; Harris et al., 2018; Jacobs et al., 2018a; Das et al., 2019; Walker et al., 2019; Molloy et al., 2020). Landscape planning (Bond et al., 2014; McCormack, 2018) helps reduce habitat loss and facilitates species dispersal and gene flow (McLean et al., 2014; Shoo et al., 2014; Lowe et al., 2015; Harris et al., 2018; McCormack, 2018) and allows for new ecological opportunities (Norman and Christidis, 2016). Coastal squeeze is a threat to freshwater wetlands and requires planning for the potential inland shift (Grieger et al., 2019). Adaptations that maintain critical volumes and periodicity of environmental flows will help protect freshwater biodiversity (Yen et al., 2013; Barnett et al., 2015; Wang et al., 2018b) (Box 11.3).

Adaptation planning for ecosystems and species requires monitoring and evaluation to identify trigger points and thresholds for new actions to be implemented *(high confidence)* (Tanner-McAllister et al., 2017; Williams et al., 2020). Best planning practice includes keeping options open (Barnett et al., 2015; Dunlop et al., 2016; Finlayson et al., 2017) and updating management plans in light of new information. New insights are emerging into how species' natural adaptive capacities can inform adaptation planning (Llewelyn et al., 2016; Steane et al., 2017; Hoeppner and Hughes, 2019). Physiological limits to adaptation in some species are being identified (Barnett et al., 2015; Sorensen et al., 2016) and where natural responses are not feasible, human-assisted translocations may be warranted (Becker et al., 2013; Chauvenet et al., 2013; Innes et al., 2019) for some species (Ofori et al., 2017a; Ofori et al., 2017b). Legal reform may be needed to better enable climate adaptation for biodiversity conservation that recognises species' natural adjustments to their distributions, and the difficulties in predicting the consequences for ecological interactions and ecosystem services (McCormack, 2018; McDonald et al., 2019).

Adaptation research priorities include understanding of the interactions and cumulative impacts of existing stressors and climate change, and the implications for managing ecosystems and natural resources (Williams et al., 2020). For Australia, research on implementation strategies for conservation and managing threats, stress and natural assets is a priority (Williams et al., 2020). For New Zealand, understanding how terrestrial ecosystems and species respond to climate change is a priority and where existing stressors are affecting freshwater quantity and quality, in-situ monitoring to detect and evaluate projections of climate change impacts on biodiversity, and a national data repository are lacking (MfE, 2020a). The projected increase in invasive species indicates the importance of a step up in pest management effort to ensure native species persistence as invasive species spread from climate change (Firn et al., 2015). There remains a gap between the knowledge generated, potential adaptation strategies, and their incorporation into conservation instruments (*medium confidence*) (Graham et al., 2019; Hoeppner and Hughes, 2019), though there is increasing recognition of the need to improve governance and management structures for their implementation (Christie et al., 2020).

[START BOX 11.1 HERE]

Box 11.1: Escalating Impacts and Risks of Wildfire

Fire activity depends on weather, ignition sources, land management practices, and fuel flammability, availability and continuity (Bradstock et al., 2014). Increased fire activity in southeast Australia associated with climate change has been observed since 1950 (Abram et al., 2021) but trends vary regionally (Bradstock et al., 2014) (*medium confidence*). In New Zealand, there has been an increased frequency of major wildfires in plantations (FENZ, 2018) and at the rural-urban interface (Pearce, 2018) (*medium confidence*). In northern Australia, increased wet season rainfall (Gallego et al., 2017) has increased dry season fuel loads (Harris et al., 2008).

In Australia, the frequency and severity of dangerous fire weather conditions is increasing, with partial attribution to climate change (*very high confidence*) (Dowdy and Pepler, 2018; Abram et al., 2021) (11.2.1,

Figure Box 11.1.1), especially in southern and eastern Australia during spring and summer (Harris and Lucas, 2019). Although Australia's eucalypt forests and woodlands are fire adapted (Collins, 2020), increasing intensity and frequency of fires may exceed their resilience due to shorter intervals between high-severity fires (Bowman et al., 2014; Etchells et al., 2020; Lindenmayer and Taylor, 2020a). Recent fires have severely impacted eastern rainforests, including significant Gondwana refugia (Abram et al., 2021). In New Zealand, the trends in very high and extreme fire weather (1997–2019) have not yet been attributed to climate change (MfE, 2020a).

Fire weather is projected to increase in frequency, severity and duration for southern and eastern Australia (*high confidence*) and most of New Zealand (*medium confidence*) (11.2.2), with projected increases in pyro-convection risk for parts of southern Australia (Dowdy et al., 2019) and increased dry-lightning and fire ignition for southeast Australia (Mariani et al., 2019; Dowdy, 2020). Increased fire risk in spring may reduce opportunities for prescribed fuel-reduction burning in some regions (Harris and Lucas, 2019; Di Virgilio et al., 2020). Fuel dryness is a key constraint on wildfire occurrence (Ruthrof et al., 2016). Vegetation change will affect fuel load and fire risk in different areas in complex ways (Watt et al., 2019; Alexandra and Max Finlayson, 2020; Clarke et al., 2020; Sanderson and Fisher, 2020).

Direct effects of wildfire include death and injury to people and animals, and damage to ecosystems, property, agriculture, water supplies and other infrastructure (Brodison, 2013; Pearce, 2018; de Jesus et al., 2020; Johnston et al., 2020; Maybery et al., 2020). Indirect effects include electricity and communication blackouts leading to cascading impacts on services, infrastructure and communities (Bowman, 2012; Schavemaker and van der Sluis, 2017).

For New Zealand, there has been recent increased frequency and magnitude of property losses due to wildfire (Pearce, 2018). The 1660ha Port Hills fire in 2017 resulted in the greatest house losses (9) in almost 100 years (Langer et al., 2018), but the subsequent 5540ha Lake Ohau fire destroyed 53 houses in 2020 (Waitaki District Council, 2020).

In Australia, between 1987 and 2016, there were 218 deaths, 1,000 injuries, 2,600 people left homeless and 69,000 people affected by wildfire (Deloitte, 2017b). Wildfires cost about $1.1 billion per year on average (11.5.2).

The Australian wildfires of 2019–2020 resulted in 33 deaths, over 3,000 houses destroyed, $2.3 billion in insured losses, and $3.6 billion in losses for tourism, hospitality, agriculture and forestry (CoA, 2020e; Filkov et al., 2020) (Figure Box 11.1.2). Smoke caused a further 429 deaths and 3230 hospitalizations as a result of respiratory distress and illness, with health costs totalling $1.95 billion (Johnston et al., 2020). These fires burnt about 5.8 to 8.1 million hectares of forest in eastern Australia (Ward et al., 2020; Godfree et al., 2021) resulting in the loss or displacement of nearly 3 billion vertebrate animals (CoA, 2020e; Wintle et al., 2020). 114 listed threatened species lost at least 50% of their habitat, and 49 lost 80% (Wintle et al., 2020) among other severe ecological impacts (Hyman et al., 2020). Smoke carried over 4,000 km to New Zealand where it increased snow/glacier melt through darkening surfaces and produced detectable odour (Pu et al. 2021)(Filkov et al., 2020). The fire season of 2019–20 was at least 30% more likely than a century ago due to the influence of climate change (van Oldenborgh et al., 2021). Following the fires, a Royal Commission into National Natural Disaster Arrangements made 80 recommendations, most of which were accepted by government, including establishing a disaster advisory body and a resilience and recovery agency (11.5.2.3) (CoA, 2020e).

In the face of climate change and the increased cost of fire damage and suppression, there has been considerable investment in fire risk reduction (Table Box 11.1.1). Recent analysis of 8,800 fires in Australia shows resource constraints in response capacity are a barrier to effectively containing fires (Collins et al., 2018b), compounded by lengthened and more extreme fire seasons.

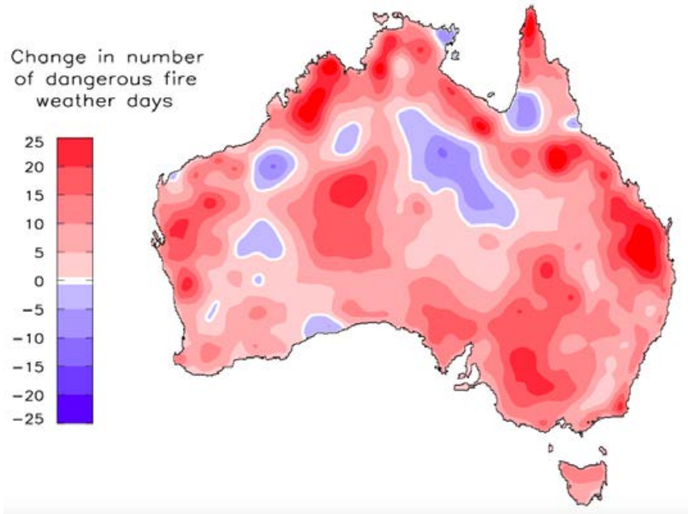

Figure Box 11.1.1: Change in the annual (July to June) number of days that the Forest Fire Danger Index (FFDI) exceeds its 90th percentile from July 1985 to June 2020 relative to July 1950 to June 1985 (BoM and CSIRO, 2020; Abram et al., 2021).

Fires in southern and eastern Australia from Sep 2019 to Feb 2020

KEY

A. Extreme air pollution

B. 5.8 to 8.1 million hectares burned with net emissions of up to 830 million tonnes of CO_2-eq

C. Respiratory illness and disruption of outdoor activities and transport

D. Massive fire-fighting effort, saving many lives and at least 16,000 buildings

E. Building and facility closures, sporting events cancelled, holidays cancelled, workplace closures

F. Degraded and destroyed:
- Wineries
- Fruit
- Livestock
- Dairy
- Plantations

G. Loss of or displacement of 3 billion animals, with possible extinctions

H. Change in framework vegetation species and depletion of vegetation habitat resources

I. Smoke and ash transported to New Zealand, affecting air quality and glaciers

J. Destroyed and damaged utilities and infrastructure, e.g. roads closed for weeks, power and communication outages, fuel shortages, back-up generators without diesel, phone batteries run flat

K. Emergency evacuations of thousands of people by road, sea and air involving State Emergency Services and National Defence Force

L. Contamination of rivers and water supply with ash and sediment

M. **Economic impacts:** Estimates of the national financial impacts are over $8 billion

N. **Social impacts:** 33 people killed by fires, 429 killed by smoke, 3,103 houses destroyed, social disruption, injuries, exhaustion and mental health issues

O. **Environmental impacts:** Loss of ecosystem service benefits

Figure Box 11.1.2: Cascading impacts on people, economic activity, built assets, ecosystems and species arising from the Black Summer fires of 2019–2020 in eastern and southern Australia (Boer et al., 2020; CoA, 2020e; CoA, 2020b; CoA, 2020a; CSIRO, 2020; Filkov et al., 2020; Johnston et al., 2020; Ward et al., 2020; Wintle et al., 2020; Abram et al., 2021; Godfree et al., 2021).

Table Box 11.1.1: Examples of adaptation options and enablers to reduce wildfire risk (Hart and Langer, 2011; Mitchell, 2013; Price et al., 2015; Tolhurst and McCarthy, 2016; Deloitte, 2017b; Miller et al., 2017; Steffen et al., 2017; Kornakova and Glavovic, 2018; Newton et al., 2018; Pearce, 2018; CoA, 2020e; McKemey et al., 2020).

Land management
Prescribed burning to reduce fuel load close to built assets.
Engagement with Australia's Aboriginal and Torres Strait Islander Peoples to utilise and learn from their fire management knowledge and skills to assist in management of the landscape and greenhouse gas mitigation.
Locating power lines appropriately or underground and decentralizing power supply to reduce ignitions.
Preventative, community-based interventions to reduce ignitions from arson and accidental fires.
Reduced exposure of new assets through statutory spatial planning and land use regulations, building codes and building design standards.
Communications
Clearer communication of existing exposure and vulnerability to enable informed decisions about risk tolerance and management. This should include sites of key biodiversity that are sensitive or susceptible to fire.
Increased research to understand interactions between fire, fuel, weather, climate and human factors to enhance projections of fire occurrence and behaviour.
Community education and engagement, encouraging house and property maintenance, improving early warning systems, more targeted messaging, and increased emergency evacuation planning and sheltering options.
Infrastructure
Enhanced training and support for fire-fighters and aerial fire-fighting assets, including sharing of resources nationally and internationally to address the increasing overlap of fire seasons which are lengthening across the world.
Nationally consistent response to exceedance of air quality standards.
Improved governance arrangements to ensure greater accountability and coordination between agencies, sharing of data and resources for emergency planning, and greater understanding of risks to critical infrastructure and supply chains.
Development of new systems to augment capability of fire services and technological advances to detect and respond to fires.

[END BOX 11.1 HERE]

11.3.2 Coastal and Ocean Ecosystems

Australia's EEZ covers over 8.1 million km^2 of marine territory, including 50,000 km of coastline (Dhanjal-Adams et al., 2016), spanning sub-Antarctic islands in the south to tropical waters in the north. New Zealand's marine territory extends from the sub-tropics to sub-Antarctic waters, encompassing an EEZ of 4 million km^2, 18,000 km of coastline and 700 smaller islands and islets, in addition to the two main islands (Costello et al., 2010a; MfE, 2016).

The marine environment is important to the culture, health and well-being of the region's diverse Indigenous Peoples, including those who had sovereign ownership, governance, resource rights, and stewardship over 'Sea Country' for many thousands of years before the current sea level stabilised approximately 6000 years ago and before current coastal ecosystems were established (Rist et al., 2019). Marine environments contribute A$69 billion per year to Australia's economy (Eadie et al., 2011), and NZ$4 billion per year to New Zealand's economy (MfE, 2016). They have a high proportion of rare and endemic species (Croxall et al., 2012) and provide ecosystem services including food production, coastal protection, tourism and carbon sequestration (Croxall et al., 2012; Kelleway et al., 2017). Half of the species within New Zealand's seas are endemic (Costello et al., 2010b).

11.3.2.1 Observed Impacts

Climate change is having major impacts on the region's oceans (*very high confidence*) (Table 11.6) (Law et al., 2016; Sutton and Bowen, 2019). Rising sea surface temperatures have exacerbated marine heatwaves, notably near Western Australia in 2011, the Great Barrier Reef in 2016, 2017 and 2020, and the Tasman Sea in 2015/2016, 2017/2018 and 2018/19 (Table 11.2) (BoM and CSIRO, 2018; AMS, 2019; NIWA, 2019; Salinger et al., 2019b; Sutton and Bowen, 2019; BoM, 2020a; Salinger et al., 2020; Oliver et al., 2021). Temperature anomalies ranged from 1.2-4.0˚C and durations ranged from 90-250 days (Table 11.2).

Ocean carbon storage and acidification has led to decreased surface pH in the region (Table 11.2) including the sub-Antarctic waters off the East Coast of New Zealand's South Island (*very high confidence*) (Law et al., 2016). The depth of the Aragonite Saturation Horizon has shallowed by 50–100 m over much of New Zealand, which may limit and/or increase the energetic costs of growth of calcifying species (Anderson et al., 2015; Bostock et al., 2015; Mikaloff-Fletcher et al., 2017) (*low confidence*).

In the estuaries of south-western Australia, sustained warming and drying trends have caused dramatic declines in freshwater flows of up to 70% since the 1970s, and increased frequency and severity of hypersaline conditions; enhanced water column stratification and hypoxia; and reduced flushing and greater retention of nutrients (Hallett et al., 2017).

Extensive changes in the life history and distribution of species have been observed in Australia's (*very high confidence*) (Gervais et al., 2021) and New Zealand's marine systems (*medium confidence*) (Table 11.6) (Cross-Chapter box MOVING SPECIES in Chapter 5). New occurrences or increased prevalence of disease, toxins and viruses are evident (de Kantzow et al., 2017; Condie et al., 2019), along with heat stress mortalities and changes in community composition (Wernberg et al., 2016; Zarco-Perello et al., 2017; Thomsen et al., 2019). Extreme climatic events in Australia from 2011 to 2017 led to abrupt and extensive mortality of key habitat-forming organisms – corals, kelps, seagrasses, and mangroves – along over 45% of the continental coastline of Australia (*high confidence*) (Babcock et al., 2019).

In 2016 and 2017, the Great Barrier Reef (GBR) experienced consecutive occurrences of the most severe coral bleaching in recorded history (*very high confidence*) (Box 11.2), with shallow-water reef in the top two thirds of the GBR affected and the severity of bleaching on individual reefs tightly correlated with the level of local heat exposure (Hughes et al., 2018b; Hughes et al., 2019c). Mass mortality of corals from these two unprecedented events resulted in larval recruitment in 2018 declining by 89% compared to historical levels (Hughes et al., 2019b). Southern reefs were also affected by warming, although significantly less than in the north (Kennedy et al., 2018). Coral reefs in Australia are at very high risk of continued negative effects on ecosystem structure and function (Hughes et al., 2019b) (*very high confidence*), cultural well-being (Goldberg et al., 2016; Lyons et al., 2019) (*very high confidence*), food provision (Hoegh-Guldberg et al., 2017) (*medium confidence*), coastal protection (Ferrario et al., 2014) (*high confidence*) and tourism (Deloitte Access Economics, 2017; Prideaux and Pabel, 2018; GBRMPA, 2019) (*high confidence*). If bleaching persists, an estimated 10,000 jobs and A$1 billion in revenue would be lost per year from declines in tourism alone (Swann and Campbell, 2016).

11.3.2.2 Projected Impacts

Future ocean warming, coupled with periodic extreme heat events, is projected to lead to the continued loss of ecosystem services and ecological functions (*high confidence*) (Smale et al., 2019), as species further shift their distributions and/or decline in abundance (Day et al., 2018). Compounding climate-driven changes in the distribution of habitat forming species, invasive macroalgae are predicted to exhibit higher growth under all higher pCO_2 and lower pH conditions (Roth-Schulze et al., 2018). Corals and mangroves around northern Australia and kelp and seagrass around southern Australia are of critical importance for ecosystem structure and function, fisheries productivity, coastal protection and carbon sequestration; these ecosystem services are therefore *extremely likely*[2] to decline with continued warming. Equally, many species provide important ecosystem structure and function in New Zealand's seas including in the deep sea (Tracey and Hjorvarsdottir, 2019). The future level of sustainable exploitation of fisheries is dependent on how climate change impacts these ecosystems. Native kelp is projected to further decline in south-eastern New Zealand with warming seas (Table 11.6). Climate change could affect New Zealand fisheries' productivity (Cummings et al., 2021), and both ocean warming and acidification may directly affect shellfish culture (Cunningham et al., 2016; Cummings et al., 2019), and indirectly through changes in phytoplankton production (Pinkerton, 2017).

Climate change related temperature and acidification may affect species sex ratios and thus population viability (*medium confidence*) (Table 11.3) (Law et al., 2016; Tait et al., 2016; Mikaloff-Fletcher et al., 2017). Acidification may alter sex determination (e.g., in the oyster *Saccostrea glomerate*), resulting in changes in sex ratios (Parker et al., 2018), and may thus affect reproductive success (*low confidence*). Decreasing river flows (Chiew et al., 2017) are projected to cause periodically open estuaries across south-west Australia to remain closed for longer periods, inhibiting the extent to which marine taxa can access these systems (Hallett et al., 2017) and with warming predicted to constrain activity in some large fish (Scott et al., 2019b). Major knowledge gaps include environmental tolerances of key life stages, sources of recruitment, population linkages, critical ecological (e.g., predator–prey interactions) or phenological relationships, and projected responses to lowered pH (Fleming et al., 2014; Fogarty et al., 2019).

Black-browed albatrosses breeding on Macquarie Island may be more vulnerable to future climate-driven changes to weather patterns in the Southern Ocean, and potential latitudinal shifts in the sub-Antarctic Front (Cleeland et al., 2019). New Zealand coastal ecosystems face risks from sea-level rise and extreme weather events (MfE, 2020a).

Nutrient availability and productivity in sub-tropical waters of New Zealand are projected to decline due to increased sea surface temperature and strengthening of the thermocline, but may increase in sub-Antarctic waters, potentially bringing some benefit to fish and other species (*low confidence*) (Law et al., 2018b). For New Zealand waters as a whole, declines in net primary productivity of 1.2% and 4.5% are projected under RCP4.5 and RCP8.5 respectively by 2100, and declines in primary production of surface waters by an average 6% from the present day under RCP8.5, with sub-tropical waters experiencing the largest decline (Tait et al., 2016).

The pH of surface waters around New Zealand is projected to decline by 0.33 under RCP 8.5 by 2090 (Tait et al., 2016), and the depth at which carbonate dissolves is projected to be significantly shallower (Mikaloff-Fletcher et al., 2017) affecting the distribution of some species of calcifying cold water corals (Law et al., 2016) (*medium confidence*). However, model projections suggest that the top of the Chatham Rise may provide temporary refugia for scleractinian stony corals from ocean acidification because the Chatham Rise sits above the aragonite saturation horizon (Anderson et al., 2015; Bostock et al., 2015). For sub-tropical corals, skeletal formation will be vulnerable to the changes in ocean pH with implications for their longer-term growth and resilience (Foster et al., 2015).

11.3.2.3 Adaptation

Climate change adaptation opportunities and pathways have been identified across aquaculture, fisheries, conservation and tourism sectors in the region (MacDiarmid et al., 2013; Fleming et al., 2014; MPI, 2015; Jennings et al., 2016; MfE, 2016; Royal Society Te Apārangi, 2017; Ling and Hobday, 2019) and some stakeholders are already autonomously adapting (Pecl et al., 2019). Some fishing and aquaculture industries use seasonal forecasts of environmental conditions, to improve decision making, risk management, and business planning (Hobday et al., 2016) with potential to use 5-yearly forecasts similarly (Champion et al., 2019). Shifts in the distribution, and availability of target species (e.g., oceanic tuna) would impact the

[2] In this Report, the following summary terms are used to describe the available evidence: limited, medium, or robust; and for the degree of agreement: low, medium, or high. A level of confidence is expressed using five qualifiers: very low, low, medium, high, and very high, and typeset in italics, e.g., *medium confidence*. For a given evidence and agreement statement, different confidence levels can be assigned, but increasing levels of evidence and degrees of agreement are correlated with increasing confidence.

ability of domestic fishing vessels to continue current fishing practices, with potential social and economic adjustment costs (Dell et al., 2015), including disruption to supply chains (Fleming et al., 2014; Plagányi et al., 2014) (Cross-Chapter Box MOVING SPECIES in Chapter 5). Species abundance data are insufficient to enable projections of climate impacts on fishery productivity. However, fishery and aquaculture industries are considering adaptation strategies, such as changing harvests and relocating farms (Pinkerton, 2017). Thus, while climate change is *extremely likely* to affect the abundance and distribution of marine species around New Zealand, insufficient monitoring means there is limited evidence of ecosystem level change in biodiversity to date, and no quantitative projections of which species may win and lose to climate change (Table 11.6) (Law et al., 2018a; Law et al., 2018b).

Table 11.6: Observed climate-change related changes in the marine ecosystems of Australia and New Zealand. Climate-related impacts have been documented at a range of scales from single species or region-specific studies, to multi-species or community-level changes.

Type of change	Examples	Climate-related Pressure	Source
Australia			
Reduced activity and increased energetic demands	Coral trout (*Plectropomus leopardus*) one of Australia's most important commercial and recreational tropical finfish species	Increased temperature (experimental laboratory study) and ocean warming	(Johansen et al., 2014; Scott et al., 2017)
Estuaries warming and freshening	Australian lagoons and rivers warming and decreasing pH at a faster rate than predicted by climate models	Warming and reduction in rainfall (leading to reduced flows and therefore being less frequently open to the sea)	(Scanes et al., 2020)
Changes in life-history traits, behaviour or recruitment	Reduced size of Sydney rock oysters (for commercial sale)	Limited capacity to bio mineralize under acidification conditions	(Fitzer et al., 2018)
	Reduced growth in tiger flathead fish in equatorward range	Ocean warming	(Morrongiello and Thresher, 2015)
	55% of 335 fish species became smaller and 45% became larger as seas warmed around Australia	Ocean warming (over three decades)	(Audzijonyte et al., 2020)
	Rock lobster display reduced avoidance of predators at 23°C compared to 20°C	Increased temperature (experimental laboratory study)	(Briceño et al., 2020)
	Analysis of stress rings in cores of corals from the Great Barrier Reef dating back to 1815, found that following bleaching events, the coral was less affected by subsequent marine heatwaves.	Heat events	(DeCarlo et al., 2019)
	Mortality and reductions in spawning stocks of fishery important abalone, prawns, rock lobsters	2011 marine heatwave	(Caputi et al., 2019)

	Recruitment of coral on GBR reduced to 11% of long-term average	Warming-driven back-to-back global bleaching events	(Hughes et al., 2019b)
	Green turtle hatchlings from southern GBR 65-69% female and hatchlings from northern GBR 100% female for last two decades	Increased sand temperatures	(Jensen et al., 2018)
New diseases, toxins	First occurrence of the virulent virus causing Pacific Oyster Mortality Syndrome (POMS), up to 90% of all farmed oysters died in impacted areas	Detected during heatwave	(de Kantzow et al., 2017)
	Mussels, scallops, oysters, clams, abalone and rock lobsters on the east coast of Tasmania found to have high levels of Paralytic Shellfish Toxins, originating from a bloom of the harmful *Alexandrium tamarense*	Warming and extension of the East Australian Current	(Hallegraeff and Bolch, 2016)
	Range expansion of phytoplankton *Noctiluca* which can be toxic	Warming and extension of the East Australian Current	(Hallegraeff et al., 2020)
	Mortality fish following algal blooms in South Australia	2013 marine heatwave	(Roberts et al., 2019)
Changes in species distributions	Range extensions at the poleward range limit have been detected in: Fish, Cephalopods, Crustaceans, Nudibranchs, Urchins, Corals.	Ocean warming	(Baird et al., 2012; Robinson et al., 2015; Sunday et al., 2015; Ling et al., 2018; Nimbs and Smith, 2018; Ramos et al., 2018; Smith et al., 2019; Caswell et al., 2020)
	Contractions in range at the equatorward range edge have been detected in: Anemones, Asteroids, Gastropods, Mussels, Algae.	Ocean warming	(Pitt et al., 2010; Poloczanska et al., 2011; Smale et al., 2019)
	Australia's most southern dominant reef building coral, *Plesiastrea versipora* in eastern Bass Strait, increasing in abundance at the poleward edge of the species' range, and also in Western Australia	Ocean warming	(Tuckett et al., 2017; Ling et al., 2018)
	South-west Australia fish assemblages- warm water fish increasing in density at poleward edge of distributions and cool-water species decrease in density at equatorward edge of distributions; increase in warm-water habitat forming species leading to reduced habitat for invertebrate assemblages	Combination of increased temperatures and changes in habitat-forming algal species	(Shalders et al., 2018; Teagle et al., 2018)
	Predicted reduction range of rare W*ilsonia humilis* herb in Tasmanian saltmarsh but no change in rest of community	Wetter and drier climate	(Prahalad and Kirkpatrick, 2019)

Changes in abundance	Shift towards a zooplankton community dominated by warm-water small copepods in south-east Australia	Ocean warming	(Kelly et al., 2016)
	Diebacks of tidal wetland mangroves	2015–2016 heatwaves combined with moisture stress	(Duke et al., 2017)
	Decline in giant kelp in Tasmania, Australia. Less than 10% remaining. Loss of kelp Australia-wide totalling at least 140,187 ha	Ocean warming & change in East Australian Current (lower nutrients)	(Wahl et al., 2015; Butler et al., 2020; Filbee-Dexter and Wernberg, 2020)
	Regional loss of seagrass in Shark Bay World Heritage Area, Western Australia	High air and water temperatures during 2011 heatwave	(Strydom et al., 2020)
	Increased annual dugong and inshore dolphin mortality across Queensland	Sustained low air temperature and increased freshwater discharge during high SOI (ENSO) index	(Meager and Limpus, 2014)
	Predict equatorward decline and poleward shift of sea urchin in eastern Australia	Ocean warming	(Castro et al., 2020)
	Increasing mortality of Australian fur seal pups in low-lying colonies	Storm surges and high tides amplified by ongoing sea-level rise	(McLean et al., 2018) (Box 11.6)
Rapid shifts in community composition, structure and integrity	Community-wide tropicalization in Australian temperate reef communities. Temperate species replaced by seaweeds, invertebrates, corals, and fishes characteristic of subtropical and tropical waters	Extreme marine heatwaves led to a 100-km range contraction of extensive kelp forests	(Vergés et al., 2016; Wernberg et al., 2016)
	On-going declines in habitat-forming seaweeds	Climate-driven shift of tropical herbivores	(Thomson et al., 2015; Nowicki et al., 2017; Zarco-Perello et al., 2017) (Wernberg et al., 2016)
	Dieback of temperate seagrass in Shark Bay, Australia, subsequently replaced by a tropical early successional seagrass with seagrass-associated megafauna (sea turtles) declining in health status	2011 Marine heatwave	(Strydom et al., 2020)
	Increased herbivory by fish on tropicalized reefs of Western Australia	Change in species composition due to ocean warming	(Zarco-Perello et al., 2019)
	No recovery two years after coral bleaching and macro alga mortality in western Australia	2011 marine heatwave	(Bridge et al., 2014)

	Mass mortality of particular coral species on affected reefs during heatwaves on the Great Barrier Reef (eastern Australia) led to altered coral reef structure and species composition 8 months later.	2016 marine heatwave	(Hughes et al., 2018c)
	Community-wide restructuring along the Great Barrier Reef, one year after the 2016 mass bleaching event.	2016 Marine heatwave	(Stuart-Smith et al., 2018)
New Zealand			
Changes in life-history	Alteration of the shell of pāua (black footed abalone, *Haliotis iris*) under lowered pH (calcite layer thinner, greater etching of external shell surface)	Lowered pH (experimental laboratory study)	(Cummings et al., 2019)
	Decline in maximum swimming performance of kingfish and snapper	Elevated CO_2 (experimental laboratory study)	(Watson et al., 2018; McMahon et al., 2020)
	Increased mortality and faster growth in juvenile kingfish	Increased temperature	(Watson et al., 2018)
	Earlier spawning of snapper in South Island	2017–2018 heatwave	(Salinger et al., 2019b)
Increase in mortality	Heat stress mortality in salmon farms off Marlborough, New Zealand, where 20 % of the salmon stocks died	2017–18 marine heatwave	(Salinger et al., 2019b)
Changes in species distributions	Species increasingly caught further south, e.g. snapper and kingfish	Ocean warming and 2017–2018 marine heatwave	(Salinger et al., 2019b)
	Non-breeding distribution of New Zealand nesting seabird (Antarctic Prion) shifting south with long term climate inferred from stable isotopes	Climate warming	(Grecian et al., 2016)
	Less phytoplankton production in Tasman Sea but more on subtropical front	Ocean warming	(Chiswell and Sutton, 2020)
	Loss of bull kelp (*Durvillaea*) populations in southern New Zealand subsequently replaced by the introduced kelp *Undaria*	2017-18 heatwave when sea and air temperatures exceeded 23 and 30 °C respectively	(Salinger et al., 2019b; Thomsen et al., 2019; Salinger et al., 2020)

[START BOX 11.2 HERE]

Box 11.2: The Great Barrier Reef in Crisis

The Great Barrier Reef (“GBR”) is the world’s largest coral reef system, comprising 3,863 reefs over an area of 348,700 km^2, stretching for 2,300 km. The GBR is a central cornerstone of the beliefs, knowledges, Lores, languages and ways of living for over 70 geographically and culturally diverse Traditional Owner groups spanning the length of the GBR (Dale et al., 2018), and contributes an estimated A$6.4 billion per year (pre COVID) to the Australian economy, mainly via tourism. As the world's most extensive coral reef ecosystem, GBR is a globally outstanding and significant entity, with practically the entire ecosystem inscribed as World Heritage in 1981 (UNESCO, 2021).

The GBR is already severely impacted by climate change, particularly ocean warming, through more frequent and severe coral bleaching (Hughes et al., 2018b; Hughes et al., 2019c) (*very high confidence*). The worst coral bleaching event on record affected over 90% of reefs in 2016 (Hughes et al., 2018b). In the most northern 700-km-long section of the GBR in which the heat exposure was the most extreme, 50% of the coral cover on reef crests was lost within eight months (Hughes et al., 2018c). Throughout the entire GBR, including the southern third where heat exposure was minimal, the cover of corals declined by 30% between March and November 2016 (Hughes et al., 2018b). In 2017, the central third of the reef was the most severely affected and the back-to-back regional-scale bleaching events has led to an unprecedented shift in the composition of GBR coral assemblages, transforming the northern and middle sections of the reef system (Hughes et al., 2018c) to a highly degraded state *(very high confidence)*. Coral recruitment to the GBR in 2018 was reduced to only 11% of the long-term average (Hughes et al., 2019b). A mass bleaching event also occurred in 2020, making it the third event in five years (BoM, 2020a) (Figure Boxes 11.2.1 and 11.2.2).

Increased heat exposure also affects the abundance and distribution of associated fish, invertebrates and algae *(high confidence)* (Stuart-Smith et al., 2018). Thus, coral bleaching is an indicator of thermal effects on coral habitat, fauna and flora. Bleaching is expected to continue for the GBR, and Australia's other coral reef systems (*virtually certain*). Bleaching conditions are projected to occur twice each decade from 2035 and annually after 2044 under RCP8.5, and annually after 2051 under RCP4.5 (Heron et al., 2017). Three degrees of global warming would result in over six times the 2016 level of thermal stress (Lough et al., 2018).

Increases in cyclone intensity projected for this century, and other extreme weather events, will greatly accelerate coral reef degradation (Osborne et al., 2017). Additionally, through interactions between elevated ocean temperature and coastal runoff (nutrient and sediment), extreme weather events may contribute to an increased frequency and/or amplitude of crown of thorn starfish outbreaks (Uthicke et al., 2015), further reducing the spatial distribution of coral.

Recovery of coral reefs following repeated disturbance events is slow (Hughes et al., 2019b; IPCC, 2019b), and it takes at least a decade after each bleaching event for the very fastest growing corals to recover (*high confidence*) (Gilmour et al., 2013; Osborne et al., 2017). Estimates of future levels of thermal stress, measured as 'degree heating months' which incorporates both the magnitude and duration of warm season sea surface temperatures (SST) anomalies, suggest that achieving the 1.5°C Paris Agreement target would be insufficient to prevent more frequent mass bleaching events (*very high confidence*) (Lough et al., 2018), although it may reduce their occurrence (Heron et al., 2017), and occurrences of warming events similar to 2016 bleaching could be reduced by 25% (King et al., 2017).

Tourist motivations for visiting the GBR are changing, with a recent survey finding that two-thirds of tourists were visiting 'before it was gone' and a similar number were reporting damage to the reef – an example of 'last chance tourism' (Piggott-McKellar and McNamara, 2016). The Australian Government is investing A$1.9 billion to support the Great Barrier Reef through science and practical environmental outcomes including reducing other anthropogenic pressures which can suppress natural adaptive capacity (CoA, 2019b; GBRMPA, 2019). However, adaptation efforts on the Great Barrier Reef aimed specifically at climate impacts, for example, coral restoration following marine heatwave impacts (Boström-Einarsson et al., 2020) may slow the impacts of climate change in small discrete regions of the reef, or reduce short-term socio-economic ramifications, but will not prevent widespread bleaching (Condie et al. 2021).

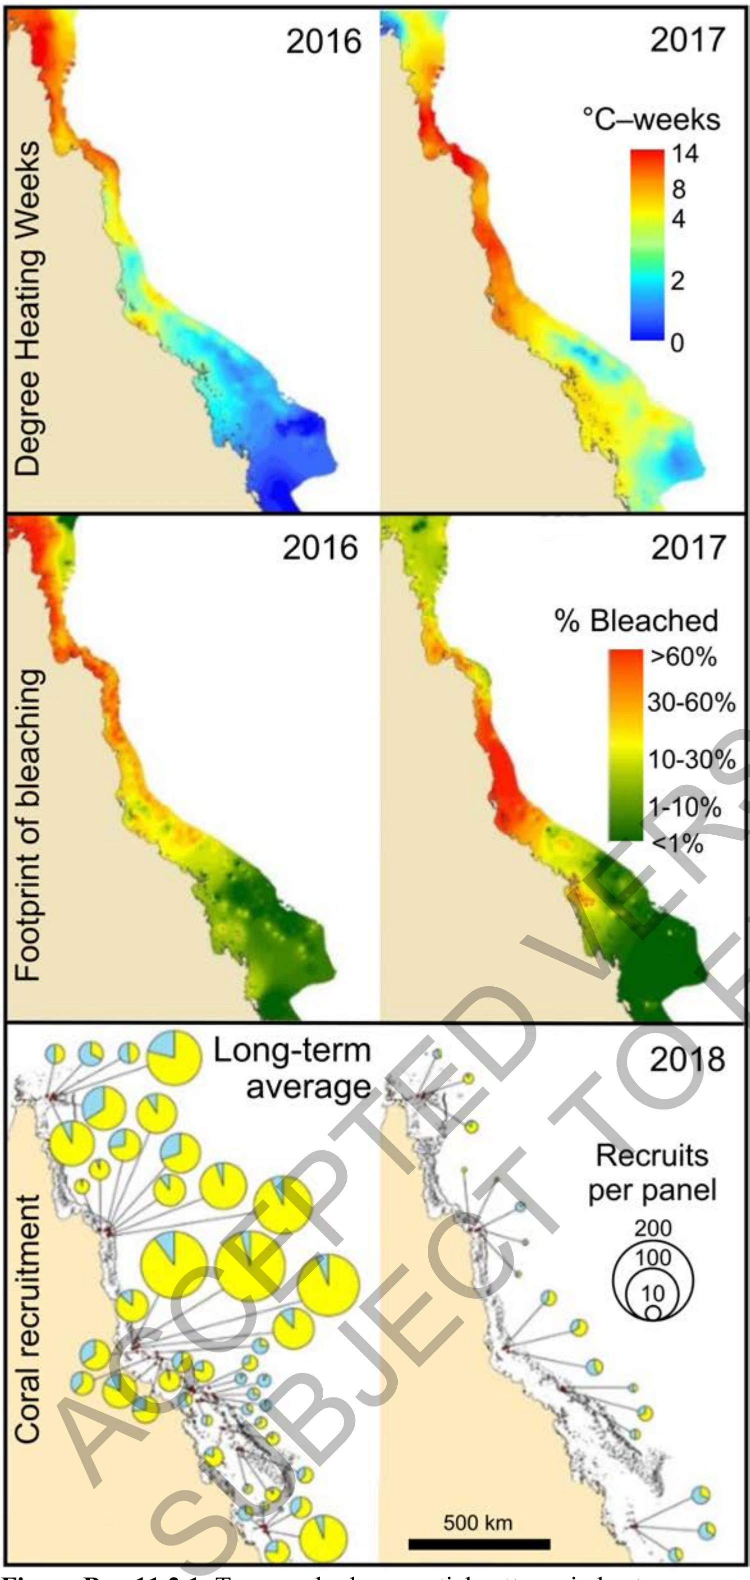

Figure Box 11.2.1: Top panels show spatial patterns in heat exposure along the Great Barrier Reef in 2016 (left) and 2017 (right), measured from satellites as Degree Heating Weeks (DHW, ºC-weeks). Middle panels show the geographic footprint of recurrent coral bleaching in 2016 (left) and again in 2017 (right), measured by aerial assessments of individual reefs (adapted from (Hughes et al., 2019c)). Bottom panels display the density of coral recruits (mean per recruitment panel on each reef), measured over three decades, from 1996 to 2016 (*n* = 47 reefs, 1,784 panels) (left), compared to the density of coral recruits in 2018 after the mass mortality of corals in 2016 and 2017 due to the back-to-back bleaching events (*n* = 17 reefs, 977 panels) (right). The area of each circle is scaled to the overall recruit density of spawners and brooders combined. Yellow and blue indicate the proportion of spawners and brooders, respectively (from (Hughes et al., 2019b)).

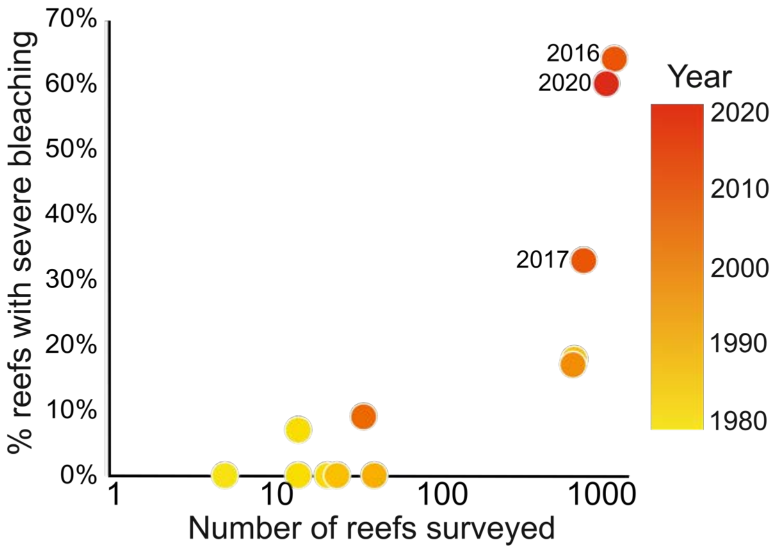

Figure Box 11.2.2: Variation in the severity of mass-bleaching episodes recorded on Australia's Great Barrier Reef over the last four decades (1980–2020). The overall number of reefs surveyed was substantially higher in 1998, 2002, 2016, 2017 and 2020 when aerial surveys were undertaken, whereas the severity of other more localised bleaching episodes was documented with in-water surveys (adapted from (Pratchett et al., 2021). Extent of bleaching in 2020 was similar in severity to 2016, but more geographically widespread and included southern reefs.

[END BOX 11.2 HERE]

11.3.3 Freshwater Resources

Climate change impacts on freshwater resources cascade across people, agriculture, industries and ecosystems (Boxes 11.3 and 11.5). The challenge of satisfying multiple demands with a finite resource is exacerbated by high inter-annual and inter-decadal variability of river flows, particularly in Australia (Chiew and McMahon, 2002; Peel et al., 2004; McKerchar et al., 2010).

11.3.3.1 Observed Impacts

Streamflow has generally increased in northern Australia and decreased in southern Australia since the mid-1970s (Zhang et al., 2016) (*high confidence*). Declining river flows since the mid-1970s in southwest Australia have led to changed water management (WA Government, 2012; WA Government, 2016). The large decline in river flows during the 1997–2009 'Millennium' drought in south-east Australia resulted in low irrigation water allocations, severe water restrictions and major environmental impacts (Potter et al., 2010; Chiew and Prosser, 2011; Leblanc et al., 2012; van Dijk et al., 2013). The drying in southern Australia highlighted the need for hydrological models that adequately account for climate change (Vaze et al., 2010; Chiew et al., 2014; Saft et al., 2016; Fowler et al., 2018). The decline in streamflow was largely due to the decline in cool season rainfall (which has been partly attributed to climate change) (Figure 11.2) (Timbal and Hendon, 2011; Post et al., 2014; Hope et al., 2017; DELWP, 2020) when most of the runoff in southern Australia occurs.

In New Zealand, precipitation has generally decreased in the north and increased in the southwest (Figure 11.2) (Harrington et al., 2014), but it is difficult to ascertain trends in the relatively short streamflow records. Glaciers in New Zealand's southern alps have lost one third of their mass since 1977 (Mackintosh et al., 2017; Salinger et al., 2019b), and glacier mass loss in 2018 was at least ten times more likely to occur with anthropogenic forcing than without (Vargo et al., 2020).

11.3.3.2 Projected Impacts

Projections indicate that future runoff in south-east and south-west Australia are *likely* to decline (median estimate of 20% and 50% respectively, under 2.2°C global average warming) (Figure 11.3) (Chiew et al., 2017; Zheng et al., 2019). These projections are broadly similar to those reported previously and in AR5 (Teng et al., 2012; Reisinger et al., 2014). The range of estimates arises mainly from the uncertainty in projected future precipitation (Table 11.2a).

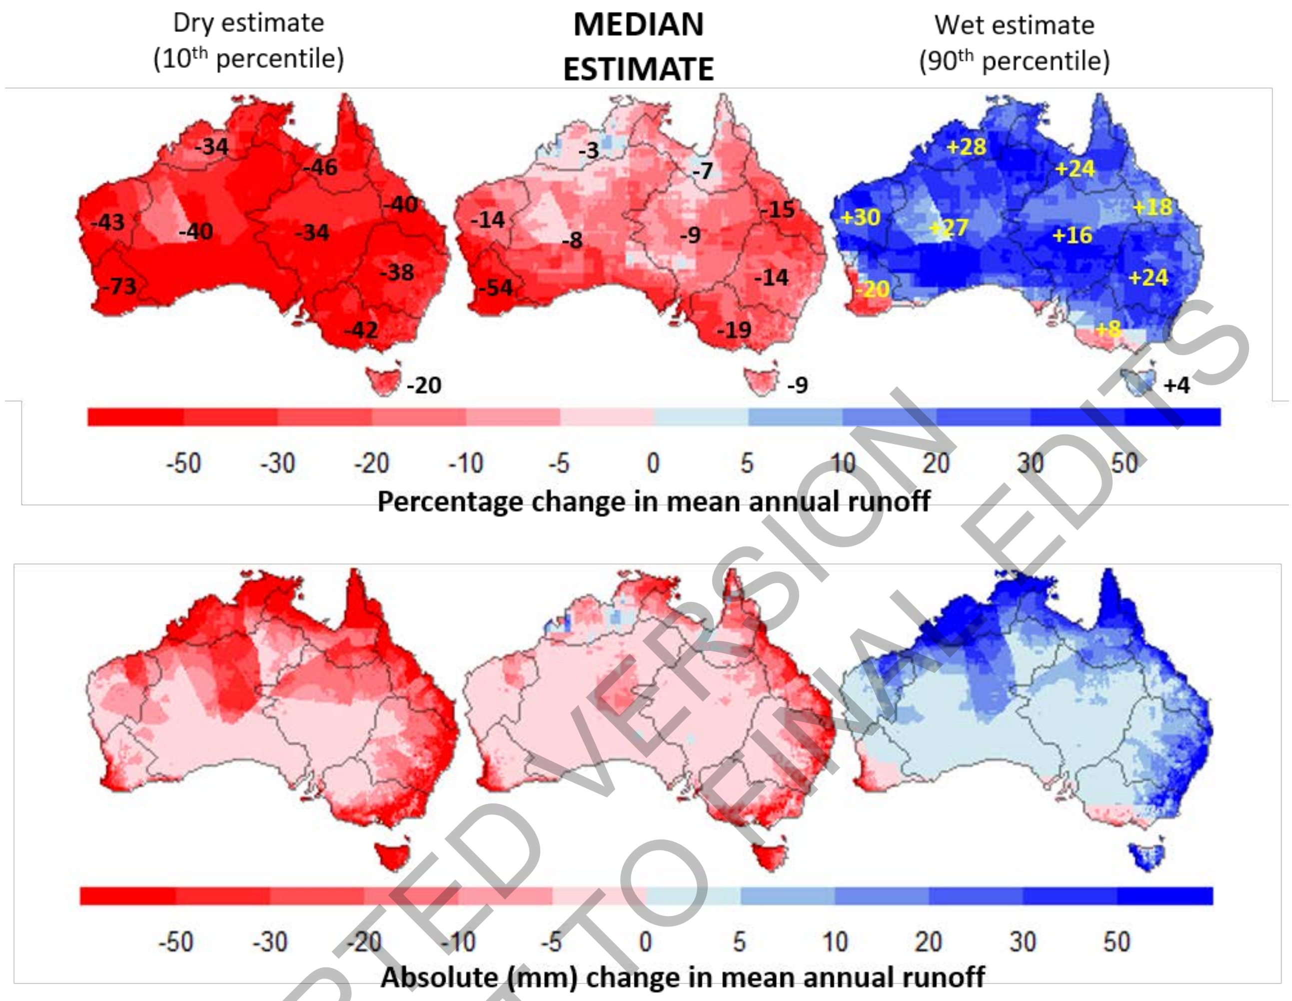

Figure 11.3: Projected changes in mean annual runoff for 2046–2075 relative to 1976–2005 for RCP8.5 from hydrological modelling with future climate projections informed by 42 CMIP5 GCMs. Projections for RCP4.5 are about three quarters of the above projections. Plots show median projection, and the 10th and 90th percentile range of estimates. The boundaries are based on hydroclimate regions and major drainage basins. Source: (Zheng et al., 2019).

The runoff decline in southern Australia is projected to be further accentuated by higher temperature and potential evapotranspiration (Potter and Chiew, 2011; Chiew et al., 2014), transpiration from tree regrowth following more frequent and severe wildfires (Brookhouse et al., 2013) (Box 11.1), interceptions from farm dams (Fowler et al., 2015), and reduced surface-groundwater connectivity (limiting groundwater discharge to rivers) in long dry spells (Petrone et al., 2010; Hughes et al., 2012; Chiew et al., 2014) (*high confidence*). In the longer-term, runoff will also be affected by changes in vegetation and surface-atmosphere feedback in a warmer and higher CO_2 environment, but the impact is uncertain because of the complex interactions including changes in climate inputs, fire patterns (Box 11.1) and nutrient availability (Raupach et al., 2013; Ukkola et al., 2016; Cheng et al., 2017).

Climate change is projected to affect groundwater recharge and the relationship between surface waters and aquifers, and through rising sea-levels where groundwater has a tidal signature (PCE, 2015; MfE, 2017a). Groundwater recharge across southern Australia has decreased in recent decades (Fu et al., 2019) and this trend is expected to continue (Barron et al., 2011; Crosbie et al., 2013) (*high confidence*). Climate change is also projected to impact water quality in rivers and water bodies, particularly through higher temperature and low flows (Jöhnk et al., 2008) (Box 11.5) and increased sediment and nutrient load following wildfires (Biswas et al., 2021) (Box 11.1) and floods (Box 11.4) (*high confidence*).

The projected changes in river flows in New Zealand are consistent with the precipitation projections (Table 11.2), with increases in the west and south of the South Island and decreases in the east and north of the North Island (Figure 11.4). In the South Island, the runoff increase occurs mainly in winter due to increasing moisture-bearing westerly airflow, with more precipitation falling as rain and snow melting earlier. In the North Island, the runoff decrease occurs in spring and summer (Caruso et al., 2017; Collins et al., 2018a; Jobst et al., 2018; D. Collins, 2020).

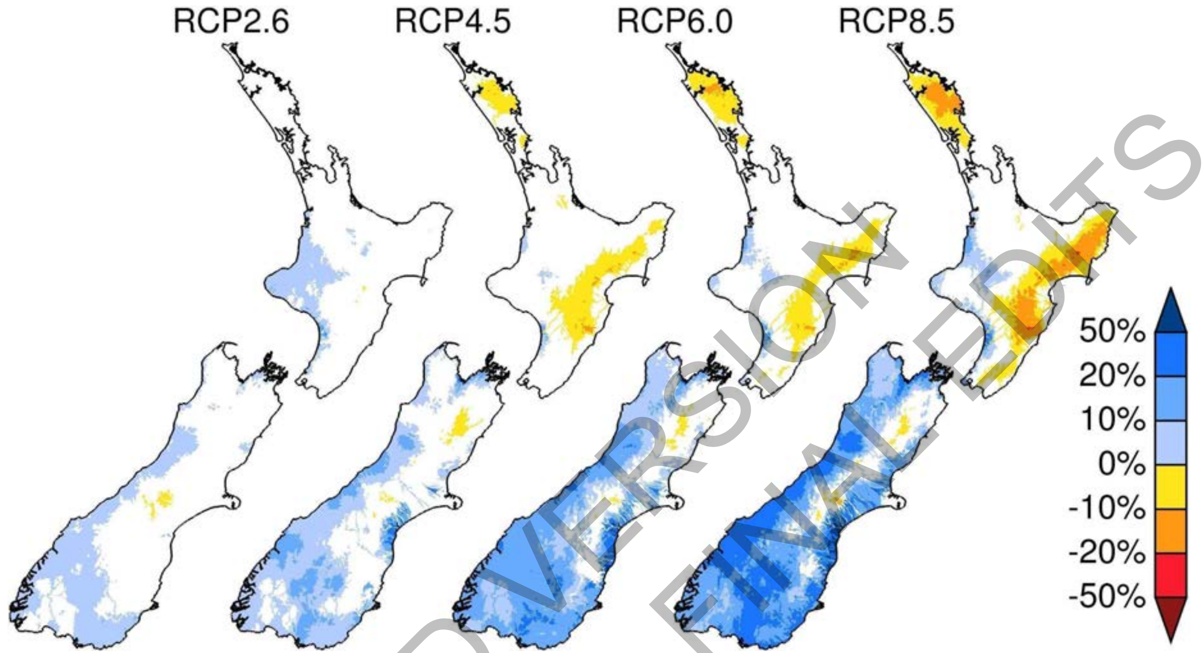

Figure 11.4: Projected percentage change in mean annual runoff for 2086–2099 relative to 1986–2005 from hydrological modelling informed by six CMIP5 GCMs for four RCPs. Maps show median projection from the six modelling runs. White indicates that the change is not statistically significant. Source: (D. Collins, 2020).

11.3.3.3 Adaptation

In Australia, prolonged droughts and projections of a drier future have accelerated policy and management change in urban and rural water systems. Adaptation initiatives and mechanisms, like significant government investment to enhance the Bureau of Meteorology online water information (Vertessy, 2013; BoM, 2016), funding to improve agriculture water use and irrigation efficiency (Koech and Langat, 2018), enhanced supply through inter-basin transfers and upgrading water infrastructure, and an active water trading market (Wheeler et al., 2013; Kirby et al., 2014; Grafton et al., 2016) are helping to buffer regional systems against droughts, and facilitating some adaptation to climate change (*medium confidence*). However, these measures could also be maladaptive as they may perpetuate unsustainable water and land uses under ongoing climate change (Boxes 11.3 and 11.5).

The widespread 2017-2019 drought across eastern Australia (BoM, 2019) has led to the Australian Government establishing a Future Drought Fund (Australian Government, 2019) to enhance drought resilience, and a National Water Grid Authority to develop regional water infrastructure to support agriculture. Nevertheless, the ability to adapt to climate change is compounded by uncertainties in future water projections, complex interactions between science, policy, community values and political voice, and competition between different sectors dependent on water (Boxes 11.3 and 11.5). The impact of declining water resource on agricultural, ecosystems and communities in south-eastern Australia would escalate with ongoing climate change (Hart, 2016; Moyle et al., 2017) (*medium confidence*), highlighting the importance of more ambitious, anticipatory, participatory and integrated adaptation responses (Bettini et al., 2015; Abel et al., 2016; Marshall and Lobry de Bruyn, 2021).

Altered water regimes resulting from the combined effects of climatic conditions and water policies carry uneven and far-reaching implications for communities (*high confidence*). Acting on Indigenous Peoples' claims to cultural flows (to maintain connection to Country) is increasingly recognised as an important water management and social justice issue (Taylor et al., 2017; Hartwig et al., 2018; Jackson, 2018; Jackson and Moggridge, 2019; Moggridge et al., 2019). Compounding stressors such as coal and coal seam gas developments can also severely impact local communities, water catchments and water-dependent ecosystems and assets, exacerbating their vulnerability to climate change (Navi et al., 2015; Tan et al., 2015; Chiew et al., 2018).

In Australian capital cities and regional centres, water planning has focused on securing new supplies that are resilient to climate change. This includes increasing use of stormwater and sewage recycling and managed aquifer recharge (Bekele et al., 2018; Page et al., 2018; Gonzalez et al., 2020). All major coastal Australian cities have desalination plants. Household scale adaptation like rainwater harvesting, water smart gardens, dual flush toilets, water-efficient showerheads and voluntary residential use targets can help reduce water demand by up to 40% (Shearer, 2011; Rhodes et al., 2012; Moglia et al., 2018). Water utilities across Australia have established climate change adaptation guidelines (WSAA, 2016). Coordinated efforts to reduce demand, design and retrofit infrastructure to reduce flood risk and harvest water, and water sensitive urban design, are evident (WSAA, 2016; Kunapo et al., 2018; Rogers et al., 2020b). Transitioning centralised water systems to a more sustainable basis represents adaptation progress but is complex and faces many barriers and limits (Morgan et al., 2020) (*medium confidence*). Developing multiple redundant or decentralised systems can enhance community resilience and promote autonomous adaptations that may be more sustainable and cost effective in the longer term (Mankad and Tapsuwan, 2011; WSAA, 2016; Iwanaga et al., 2020).

In New Zealand, many water supplies are at risk from drought, extreme rainfall events and sea-level rise, exacerbated by underinvestment in existing water infrastructure (in part due to funding constraints), and urban densification (CCATWG, 2017; MfE and StatsNz, 2021) (*high confidence*). Lessons can be learned from global experience (e.g. Cape Town, South Africa; Chapter 4.3.4). Water quality has diminished, with hotter conditions and drought causing algal blooms, combined with intensification of agricultural land uses in some areas, and heavy rainfall and sea-level rise causing flooding and sedimentation of water sources and health impacts (11.3.6; Box 11.5). Some towns are only partially metered or not metered at all, which exacerbates the adaptation challenge (Hendy et al., 2018; WaterNz, 2018; Paulik et al., 2019b). Unregulated or absent water supplies accentuate risks to vulnerable groups of people (MfE, 2020b). Māori view water as the essence of all life, which makes any impacts on water, of governance and stewardship concern, and increasingly, the subject of legal claims (MfE, 2020a; MfE, 2020b; MfE, 2020c) (11.4.2). Māori understanding of time can also open up new spaces for rethinking freshwater management in a climate change context that does not reinforce or rearticulate multiple environmental injustices (Parsons et al., 2021).

Water resource adaptation in New Zealand is variable across local government and water authorities but they all actively monitor water availability, demand and quality, and most have drought management plans. The 2019/20 drought led to water shortages in the most populated areas of Waikato, Auckland and Northland, resulting in water reduction advisories and five to eight weeks waiting time for water tank refills and water rationing. The Havelock North water supply contamination that arose after an extreme rainfall event (DIA, 2017a; DIA, 2017b) was exacerbated by fragmented governance, and led to the Taumata Arawai-Water Services Regulator Act 2020 and the Water Services Bill 2020 to protect source water. The 2017 update to the National Policy Statement for Freshwater Management with guidelines for implementation at the regional level (MfE, 2017b), including consideration of climate change which creates opportunities for adaptation. However, there remain tensions between land, water and people which are exacerbated by climate changes and yet to be addressed (Box 11.5). The first National Adaptation Plan and the Resource Management law reform have potential for helping to resolve these tensions (11.7.1) (CCATWG, 2017; MfE, 2020a).

[START BOX 11.3 HERE]

Box 11.3: Drought, Climate Change, and Water Reform in the Murray-Darling Basin

The Murray-Darling Basin (MDB) is Australia's largest, most economically important and politically complex river system (Figure Box 11.3.1). The MDB supports agriculture worth A$24 billion/year, 2.6 million people in diverse rural communities, and important environmental assets including 16 Ramsar listed wetlands (DAWE, 2021). Climate change is projected to substantially reduce water resources in the MDB (*high confidence*), with the median projection indicating a 20% decline in average annual runoff under 2.2°C average global warming (Figure 11.3) (Whetton and Chiew, 2020). This reduction, plus increased demand for water in hot and dry conditions, would increase the already intense competition for water (*high confidence*) (CSIRO, 2008; Hart, 2016).

The economic, environmental and social impacts of the 1997–2009 'Millennium Drought' in the MDB (Chiew and Prosser, 2011; Leblanc et al., 2012; van Dijk et al., 2013), and projections of a drier future under climate change, have accelerated significant water policy reforms, costing more than A$12 billion (Bark et al., 2014; Docker and Robinson, 2014; Hart, 2016). These reforms included the development of a Basin Plan (MDBA, 2011; MDBA, 2012) requiring consistent regional water resource plans (MDBA, 2011; MDBA, 2012; MDBA, 2013) and environmental watering strategies (MDBA, 2014) across the MDB. Despite contestation, the reforms have resulted in some substantive achievements, including returning an equivalent of about one fifth of consumptive water to the environment through the purchase of irrigation water entitlements and infrastructure projects (Hart, 2016; Gawne et al., 2020; MDBA, 2020) (*medium confidence*). However, the overall impacts of these water management initiatives are difficult to measure due to hydroclimatic variability, time lags and environmental, social and institutional complexity (Crase, 2011; Bark et al., 2014; Docker and Robinson, 2014; MDBA, 2020).

Reform initiatives such as water markets, improving agriculture water use efficiency (Koech and Langat, 2018), and increasing environmental water are helping buffer the system against droughts (Moyle et al., 2017) (*medium confidence*) but they can also be maladaptive by perpetuating unsustainable water and land use under ongoing climate change. While water markets can allow users to adapt and shift water to higher value uses, they can also have adverse impacts unless supported by wider policy goals and planning processes (Wheeler et al., 2013; Kirby et al., 2014; Grafton et al., 2016; Qureshi et al., 2018).

Adapting MDB management to climate risks is an escalating challenge, with the projected decline in runoff being potentially greater than the water recovered for the environment (Chiew et al., 2017). While the Basin Plan includes mechanisms for climate risks management (Neave et al., 2015), it does not require altering pre-existing rules that distribute the impacts of anticipated reductions in water resource between users (Hart, 2016; Capon and Capon, 2017; Alexandra, 2020). The intense drought conditions in 2017-2019 (BoM, 2019), the South Australian Royal Commission into the MDB reforms (SA Government, 2019b), and major fish kills in the lower Darling River in the summer of 2018/2019 (AAS, 2019; Vertessy et al., 2019) have increased concerns about the Basin Plan's climate adaptation deficit (*medium confidence*). The Murray Darling Basin Authority (MDBA) consequently is undertaking an assessment of climate change risks and developing adaptation mechanisms (MDBA, 2019) that can feed into the revisions to the Basin Plan scheduled for 2026. The MDB reforms to date illustrate the difficulties in integrating climate change science and projections into management (Alexandra, 2018; Alexandra, 2020). Anticipatory and participatory governance and adaptive management approaches supported by structural and institutional reforms would support the effectiveness of the reforms (Abel et al., 2016; Alexandra, 2019; Hassenforder and Barone, 2019; Marshall and Lobry de Bruyn, 2021).

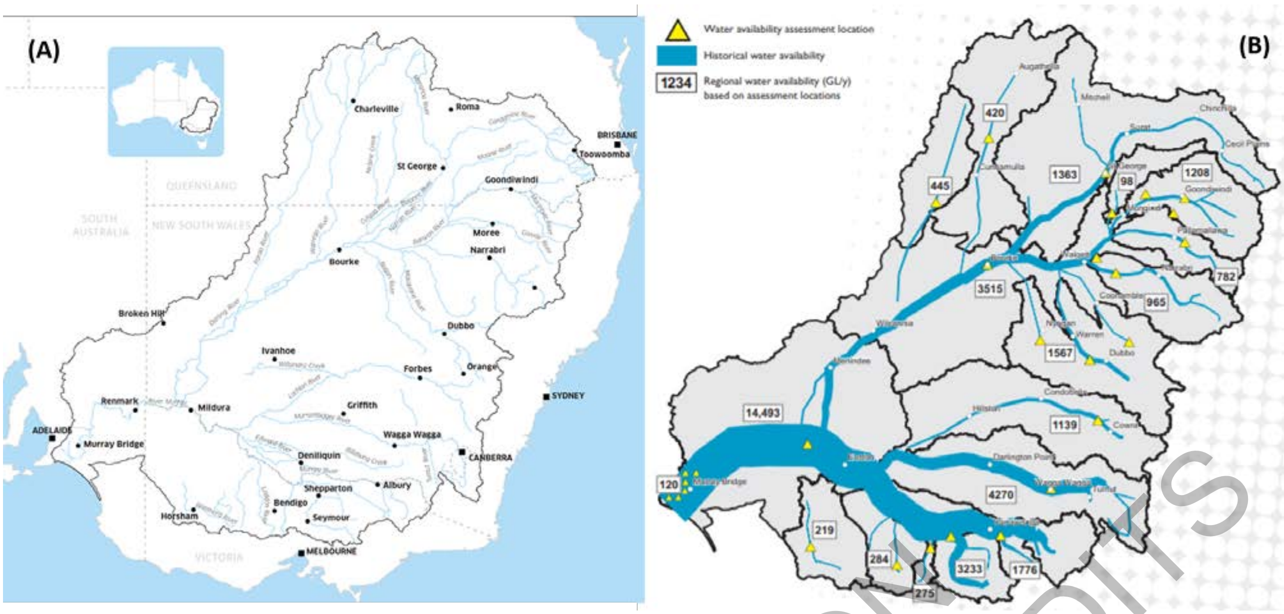

Figure Box 11.3.1: (A) The Murray-Darling Basin, and (B) average annual river flows in the Basin under pre-development conditions (from (CSIRO, 2008) showing that most of the runoff comes from the south-eastern highlands. The borders show key drainage basins.

[END BOX 11.3 HERE]

[START BOX 11.4 HERE]

Box 11.4: Changing Flood Risk

Pluvial (flash flood from high intensity rainfall) and fluvial (river) flooding are the most costly natural disasters in Australia, averaging A$8.8 billion per year (Deloitte, 2017b). In New Zealand, insured damages for the 12 costliest flood events from 2007-2017 exceeded NZ$472 million of which NZ$140 million has been attributed to anthropogenic climate change (Frame et al., 2020). Extreme rainfall intensity in northern Australia and New Zealand has been increasing, particularly for shorter (sub-daily) duration and more extreme high rainfall (*high confidence*) (Westra and Sisson, 2011; Griffiths, 2013; Laz et al., 2014; Rosier et al., 2015). Changes are also occurring in spatial and temporal patterns and seasonality (Wasko and Sharma, 2015; Zheng et al., 2015; Wasko et al., 2016).

Extreme rainfall is projected to become more intense (*high confidence*) but the magnitude of change is uncertain (Evans and McCabe, 2013; Bao et al., 2017) (Table 11.3). The insured damage in New Zealand from more intense extreme rainfall under RCP8.5 is projected to increase 25% by 2080–2100 (Pastor-Paz et al., 2020). In urban areas, extreme rainfall intensity is projected to increase pluvial flood risk (*high confidence*). In New Zealand, 20,000km^2 of land, 675,000 people, and 411,000 buildings with a NZ$135 billion replacement value are exposed to 1-in-100 year flood risk (Paulik et al., 2019a).

In non-urban areas, where the flood response is also dependent on antecedent catchment conditions (Johnson et al., 2016; Sharma et al., 2018), there is no evidence of increasing flood magnitudes in Australia (Ishak et al., 2013; Zhang et al., 2016; Bennett et al., 2018) except for the most extreme events (Sharma et al., 2018; Wasko and Nathan, 2019). Modelling studies project increases in flood magnitudes in northern and eastern Australia, and in western and northern New Zealand (*high confidence*) (Hirabayashi et al., 2013; Collins et al., 2018a; Do et al., 2020). The change in flood magnitude in southern Australia is uncertain because of the compensating effect of more intense extreme rainfall, versus projected drier antecedent conditions (Johnson et al., 2016; Pedruco et al., 2018; Wasko and Nathan, 2019). Higher rainfall intensity and peak flows also increase erosion, sediment and nutrient loads in waterways (Lough et al., 2015) and exacerbate problems from aging stormwater and wastewater infrastructure (Jollands et al., 2007; WSAA, 2016; Hughes et al., 2021).

There is some recognition of the need for flood management and planning to adapt to climate change (COAG, 2011; CCATWG, 2018; CoA, 2020d) (*medium confidence*). Australian flood estimation guidelines recommend a 5% increase in design rainfall intensity per degree global average warming (Bates et al., 2015). In New Zealand, the recommended increase ranges from 5% to more than 10% for shorter duration and longer return period storms (MfE, 2010; Carey-Smith et al., 2018). Both guidelines also indicate the potential for higher increases in extreme rainfall intensity.

Adaptation to reduce flooding and its impacts have included: improved flood forecasting (Vertessy, 2013; BoM, 2016) and risk management (AIDR, 2017); accommodating risk through raising floor levels and sealing external doors (Queensland Government, 2011; Wang et al., 2015), deployment of temporary levee structures; and risk reduction through spatial planning and relocation. Adaptation options in urban areas include improved stormwater management (Hettiarachchi et al., 2019; Matteo et al., 2019), ecosystem-based approaches such as maintaining floodplains, restoring wetlands and retrofitting existing flood control systems to attenuate flows, and water sensitive urban design (WSAA, 2016; Radcliffe et al., 2017; Radhakrishnan et al., 2017; Rogers et al., 2020b).

Adaptation to changing flood risks is currently mostly reactive and incremental in response to flood and heavy rainfall events (*high confidence*). For example, the 2010-2011 flooding in eastern Australia resulted in changes to reservoir operations to mitigate floods (QFCI, 2012) and insurance practice to cover flood damages (Phelan, 2011; Phelan et al., 2011; QFCI, 2012; Schuster, 2013). Nevertheless, adaptation planning that is pre-emptive and incorporates uncertainties into flood projections is emerging (Schumacher, 2020) (*medium confidence*). Examples from New Zealand include the use of Dynamic Adaptive Pathways Planning (Lawrence and Haasnoot, 2017) with Real Options assessment (Infometrics and PSConsulting, 2015) and design of decision signals and triggers to monitor changes before physical and coping thresholds are reached (Stephens et al., 2018). Implementing adaptive flood risk management relies upon an understanding of how such risks change in uncertain and ambiguous ways necessitating adaptive and robust decision making processes. These can enable learning through participatory adaptive pathways approaches (Lawrence and Haasnoot, 2017; Bosomworth and Gaillard, 2019) and through coordination across different levels of government and statutory mandates, adaptation funding, and individual and community adaptations (Glavovic et al., 2010; Boston and Lawrence, 2018; McNicol, 2021).

[END BOX 11.4 HERE]

11.3.4 Food, Fibre, Ecosystem Products

The food, fibre and ecosystem products sectors are economically important in the region. Agriculture contributes around 4% of New Zealand GDP and 2% of Australian GDP, and over 50% of New Zealand's and 11% of Australia's exports (NZ Treasury, 2016; Jackson et al., 2020). Forestry contributes 1% of New Zealand GDP and 0.5% Australian GDP (NZ Treasury, 2016; Whittle, 2019). With the processing and indirect effects, the primary sector of New Zealand contributes 25% of GDP (Saunders et al., 2016). The region has the lowest level of agricultural subsidies across the OECD (OECD, 2017), and highly responsive producers to market drivers but limited strategic, longer-term approaches to environmental challenges and adaptation (Wreford et al., 2019). Both countries receive government financial drought assistance (Pomeroy, 2015; Downing et al., 2016).

Impacts resulting from climate change are observed across sectors and the region (*high confidence*). While more intense changes are observed in Australia, New Zealand is also experiencing impacts, including the economic impacts of drought attributable to climate change (Frame et al. 2020). Overall, modelling indicates that negative impacts will intensify with increased levels of warming in both countries, with declining crop yield and quality, and negative effects on livestock production and forestry. Although benefits are identified, particularly in the short term for New Zealand (MfE, 2020a), an absence of studies that consider the totality of climatic variables, including extremes, moderate the benefits identified from considering only selected variables and systems in isolation.

Incremental adaptation is occurring (Hochman et al., 2017; Hughes and Lawson, 2017; Hughes and Gooday, 2021). In the longer term, transformative adaptation, including land-use change, will be required (Cradock-Henry et al., 2020a), both as a result of sectoral adaptations and mitigation (Grundy et al., 2016) (*medium confidence*). Specific changes are context specific and challenging to project (Bryan et al., 2016). Future adaptive capacity may be limited by declining institutional and community capacity resulting from high debt, unavailability of insurance, increasing regulatory requirements, and funding mechanisms that lock-in ongoing exposure to climate risk, creating mental health impacts (Rickards et al., 2014; Wiseman and Bardsley, 2016; McNamara and Buggy, 2017; McNamara et al., 2017; Moyle et al., 2017; Robinson et al., 2018; Ma et al., 2020; Yazd et al., 2020).

11.3.4.1 Field Crops and Horticulture

11.3.4.1.1 Observed impacts

Drought, heat and frost in recent decades have shown the vulnerability of Australian field crops and horticulture to climate change (Cai et al., 2014; Howden et al., 2014; CSIRO and BOM, 2015; Lobell et al., 2015; Hughes and Lawson, 2017; King et al., 2017; Webb et al., 2017; Harris et al., 2020) as recognised by policy makers (CoA, 2019a) (*high confidence*). Drought has caused economic losses attributable to climate change of at least NZ$800M in New Zealand (Frame et al., 2020). Northern Australia's agricultural output losses are on average 19% each year due to drought (Thi Tran et al., 2016). In southern Australia, the frequency of frost has been relatively unchanged since the 1980s (Dittus et al., 2014; Pepler et al., 2018; BoM and CSIRO, 2020). Drier winters have increased the irrigation requirement for wine grapes (Bonada et al., 2020) while smoke from the 2019/20 fires, which occurred early in the season, caused significant taint damage (Jiang et al., 2021). In New Zealand, reduced winter chill has a compounded impact on the kiwifruit industry, resulting in early harvest and increased energy demand for refrigeration and port access problems (Cradock-Henry et al., 2019) (11.5).

Across all types of agriculture, drought and its physical flow-on effects have caused financial and emotional disruption and stress in farm households and communities (Austin et al., 2018; Bryant and Garnham, 2018; Yazd et al., 2019) (11.3.6). Severe and uncertain climate conditions are statistically associated with increases in farmer suicide (Crnek-Georgeson et al., 2017; Perceval et al., 2019). Rural women often carry extra stress and responsibilities, including increased unpaid and paid work and emotional load (Whittenbury, 2013; Hanigan et al., 2018; Rich et al., 2018).

11.3.4.1.2 Projected impacts

Australian crop yields are projected to decline due to hotter and drier conditions, including intense heat spikes (Anwar et al., 2015; Lobell et al., 2015; Prokopy et al., 2015; Dreccer et al., 2018; Nuttall et al., 2018; Wang et al., 2018a) (*high confidence*). Interactions of heat and drought could lead to even greater losses than heat alone (Sadras and Dreccer, 2015; Hunt et al., 2018). Australian wheat yields are projected to decline by 2050, with a median yield decline of up to 30% in south-west Australia and up to 15% in South Australia, with possible increases and decreases in the east (Taylor et al., 2018, Wang, #1599; Wang et al., 2018a). In temperate fruit, accumulated winter chill for horticulture is projected to further decline (Darbyshire et al., 2016). Winegrape maturity is projected to occur earlier due to warmer temperatures (Webb et al., 2014; van Leeuwen and Darriet, 2016; Jarvis et al., 2018; Ausseil et al., 2019b) (*high confidence*) leading to potential changes in wine style (Bonada et al., 2015). Rice is susceptible to heat stress and average grain yield losses across rice varieties range from 83% to 53% in experimental trials when heat stress was applied during plant emergence and grain fill stages (Ali et al., 2019). In Tasmania, wheat yields are projected to increase, particularly at sites presently temperature-limited (Phelan et al., 2014).

New Zealand evidence on impacts across crops is very limited. Considering precipitation and temperature changes alone show minor effects on crop yield, and winter yields of some crops may increase (e.g. wheat, maize) (Ausseil et al., 2019b). For temperate fruit, loss of winter chill may reduce yields in some regions and trigger impacts across supply chains (Cradock-Henry et al., 2019) (11.5.1). Increased pathogens could damage the cut flower, guava and feijoa fruit growing, and the honey industries (Lawrence et al., 2016). The combined effects of changes in seasonality, temperature, precipitation, water availability and extremes, such as drought, have the potential to escalate impacts, but understanding of these effects is limited.

Other climate-change related factors complicate crop climate responses. When CO_2 was elevated from present-day levels of 400 ppm to 550 ppm in trials, yields of rainfed wheat, field pea and lentil increased approximately 25% (0-70%). However, there was a 6% reduction in wheat protein that could not be offset by additional nitrogen fertilizer (O'Leary et al., 2015; Fitzgerald et al., 2016; Tausz et al., 2017). Elevated CO2 will worsen some pest and disease pressures, e.g. Barley Yellow Dwarf Virus impacts on wheat (Trębicki et al., 2015). Warmer temperatures are also expanding the potential range of the Queensland fruit fly, including into New Zealand (Aguilar et al., 2015a) threatening the horticulture industry (Sultana et al., 2017; Sultana et al., 2020). Some crop pests (e.g. the oat aphid) are projected to be negatively affected by climate change (Macfadyen et al., 2018), but so too are beneficial insects. There is large uncertainty in rainfall and crop projections for northern Australia (Table 11.3). For sugarcane, impact assessment for CO_2 at 734ppm using the A2 emission scenario at Ayr in Queensland projected modest yield increases (Singels et al., 2014). Climate change are projected to adversely impact tropical fruit crops such as mangoes through higher minimum and maximum temperatures reducing the number of inductive days for flowering (Clonan et al., 2020).

Climate change is projected to shift agro-ecological zones (Lenoir and Svenning, 2015; Scheffers et al., 2016) (*high confidence*). This includes the climatically determined cropping strip bounded by the inner arid rangelands and the wetter coast or mountain ranges in mainland Australia (Nidumolu et al., 2012; Eagles et al., 2014; Tozer et al., 2014). A narrowing of grain growing regions is projected with a shift of the inner margin towards the coast under drier and warmer conditions (Nidumolu et al., 2012; Fletcher et al., 2020). The economic impact of the shift depends on adaptation (Sanderson et al., 2015; Hunt et al., 2019) and how resources, support industries, infrastructure and settlements adapt. Shifts in agro-ecological zones present some opportunities, for example, warming is projected to be beneficial for wine production in Tasmania (Harris et al., 2020).

11.3.4.1.3 Adaptation

Some farmers are adapting to drier and warmer conditions through more effective capture of non-growing season rainfall (e.g. stubble retention to store soil water), improved water use efficiency, and matching sowing times and cultivars to the environment (Kirkegaard and Hunt, 2011; Fitzer et al., 2019; Haensch et al., 2021) (*high confidence*). Observed adaptations include new technologies that improve resource efficiencies, professional knowledge and skills development, new farmer and community networks, and diversification of business and household income (Ghahramani et al., 2015; De et al., 2016). For Australian wheat, earlier sowing and longer season cultivars may increase yield by 2-4% by 2050, with a range of -7 to +2% by 2090 (Wang et al., 2018a). In the wheat industry, breeding for improved reproductive frost tolerance remains a priority (Lobell et al., 2015). Modelling suggests that, since 1990, farm management has held Australian wheat yields constant, but declining rainfall and increasing temperature may have contributed to a 27% decline in simulated potential Australian wheat yield (Hochman et al., 2017).

Other observed incremental adaptations include later pruning in the grape industry to spread harvest period and partially restore wine balance, with neutral effects on yield and cost (Moran et al., 2019; Ausseil et al., 2021). The cotton sector increasingly requires shifts in sowing dates to avoid financial impacts (Luo et al., 2017). During years of low water availability, rice growers have been trading water and/or shifting to dry land farming (Mushtaq, 2016).

Growers in New Zealand are changing the timing of their operations, growing crops within covered enclosures, and purchasing insurance (Cradock-Henry and McKusker, 2015)(Teixeira et al. 2018). Investment of capital in irrigation infrastructure has increased (Cradock-Henry et al., 2018a), although its effectiveness as an adaptation depends on water availability (Box 11.5). In industries based on long-lived plants, such as the kiwifruit and grape industries, many of the adaptations (e.g. breeding and growing heat-adapted and disease-resistant varieties) have long-lead times and require greater investment than in the cropping sector (Cradock-Henry et al., 2020a). While breeding programmes for traits with enhanced resilience to future climates are beginning, there is little evidence of strategic industry planning (Cradock-Henry et al., 2018a).

For drought management, balancing near-term needs with long-term adaptation to increasing aridity is essential (Downing et al., 2016). Insufficient and maladaptive decisions can have far-reaching effects, including changes to resources, infrastructure, services and supply chains to which others have to adapt

(Fleming et al., 2015; Graham et al., 2018). While there is potential for greater proportion of agriculture to be located to northern Australia, there are significant and complex agronomic, environmental, institutional, financial and social challenges for successful transformation including the risk of disruption (Jakku et al., 2016) (*medium confidence*).

11.3.4.2 Livestock

11.3.4.2.1 Observed impacts

Both the seasonality and annual production of pasture is changing (*high confidence*). In many regions, warming is increasing winter pasture growth (Lieffering, 2016); effects on spring growth are more mixed with some regions experiencing increased growth {(Newton et al. 2014)} and others experiencing reduced spring growth (Perera et al., 2020). Droughts are causing economic damage to livestock enterprises with drought and market prices significantly affecting profit (Hughes et al., 2019a), in addition to the impacts on animal health and the livelihoods of pastoralists, periods of drought contribute to land degradation, particularly in the cattle regions of northern Australia (Marshall, 2015). Heat load in cattle leads to reduced growth rates and reproduction, and extreme heat waves can lead to death (Lees et al., 2019; Harrington, 2020). Temperatures over 32ºC reduce ewe and ram fertility along with the birth weight of lambs (van Wettere et al., 2021).

11.3.4.2.2 Projected impacts

Some areas may experience increased pasture growth, but others may experience a decrease that cannot be fully offset by adaptation (Moore and Ghahramani, 2013; Lieffering, 2016; Kalaugher et al., 2017) (*high confidence*). Climate change may modify the seasonality of pasture growth rates more than annual yields in New Zealand (Lieffering, 2016). In eastern parts of Queensland, climate change impacts on pasture growth are equivocal, with simple empirical models suggesting a decrease in net primary productivity (Liu et al., 2017), whilst mechanistic models that include increases in length of the growing season and the beneficial effects of CO_2 fertilisation indicate increases in pasture growth (Cobon et al., 2020). In Tasmania, annual pasture production is projected to increase by 13–16%, even with summer growth projected to reduce with increased inter-annual variability, resulting in projected increase of milk yields by 3–16% per annum (Phelan et al., 2015).

Extreme climatic events (droughts, floods and heatwaves) are projected to adversely impact productivity for livestock systems (*medium confidence*). This includes reduced pasture growth rates between 3-23% by 2070 from late spring to autumn, and elevated growth in winter and early spring (Cullen et al., 2009; Hennessy et al., 2016; Chang-Fung-Martel et al., 2017). Heavy rainfall and storms are projected to lead to increased erosion, particularly in extensively grazed systems on steeper land, reducing productivity for decades, reducing soil carbon (Orwin et al., 2015), and increasing sedimentation. Increased heat stress in livestock is projected to decrease milk production and livestock reproduction rates (high confidence) (Nidumolu et al., 2014; Ausseil et al., 2019b; Lees et al., 2019). In Australia, the average number of moderate to severe heat stress days for livestock is projected to increase 12-15 days by 2025 and 31–42 days by 2050 compared to 1970-2000 (Nidumolu et al., 2014). In New Zealand, an extra 5 (RCP2.6) to 7 (RCP8.5) moderate heat stress days per year are projected for 2046-2060 (Ausseil et al., 2019b) (*high confidence*) especially affecting animals transported long distances (Zhang and Phillips, 2019) and strain the cold chains needed to deliver meat and dairy products safely. The distribution of existing and new pests and diseases are projected to increase, for example, new tick and mosquito-borne diseases such as Bovine ephemeral fever (Kean et al., 2015).

11.3.4.2.3 Adaptation

Adaptations in both grazing and confined beef cattle systems require enhanced decision-making skills capable of integrating biophysical, social and economic considerations (*high confidence*). Social learning networks that support integration of lessons learned from early adopters and involvement with science-based organizations can help enhance decision-making and climate adaptation planning (Derner et al., 2018). Pasture management adaptations for livestock production include deeper rooted pasture species in higher rainfall regions (Cullen et al., 2014) and drought tolerant species (Mathew et al., 2018). Soil and land management practices are important in ensuring soils maintain their supporting and regulating services (Orwin et al., 2015). Adaptations in the primary sector in New Zealand are now positioned within the requirements of the National Policy Statement on Freshwater (MfE, 2020b). Adaptations to manage heat stress in livestock include altering the breeding calendar, providing shade and sprinklers, altering nutrition and feeding times, and more heat-tolerant animal breeds (Chang-Fung-Martel et al., 2017; Lees et al., 2019; van Wettere et al., 2021).

Beef rangeland systems in Queensland are projected to have benefits in the south-east through higher CO_2 and temperatures extending the growing season and reducing frost, but a warmer and drier climate in the south-west may reduce pasture and livestock production (Cobon et al., 2020). Northern Queensland is most resilient to temperature and rainfall changes (production limited by soil fertility) while western/central west Queensland is most sensitive to rainfall changes. i.e. low rainfall associated with lower productivity (Cobon et al., 2020). The social context of climate change impacts and the processes shaping vulnerability and adaptation, especially at the scale of the individual, are critical to successful adaptation efforts.(Marshall and Stokes, 2014)

11.3.4.3 Forestry

11.3.4.3.1 Observed impacts

Climate change may have increased tree mortality in Australia's commercial *Eucalyptus globulus* and *Pinus radiata* plantation forests (Crous et al., 2013; Pinkard et al., 2014). Climate warming decreased fine root biomass of *E. globulus* (Quentin et al., 2015) and enhanced tree water use and vulnerability to heat (Crous et al., 2013). Increases in fire frequency and intensity in forests of southern Australia are leading to diminishing resources available for timber production (Pinkard et al., 2014) [Box 11.1].

11.3.4.3.2 Projected impacts

The projected declines in rainfall in far southwest and far southeast mainland Australia are projected to reduce plantation forest yields (*high confidence*). Warmer temperatures are projected to reduce forest growth in hotter regions (between 7-25%), especially where species are grown at the upper range of their temperature tolerances, and increase plantation forest growth (>15%) in cooler margins like Tasmania and the Victorian highlands (2030, A2); emission scenario A2 creates a warming trajectory slightly higher than the RCP6.0 warming scenario, but less than RCP8.5 (Rogelj et al., 2012; Battaglia and Bruce, 2017). Elevated CO_2 is projected to increase forest growth if other biophysical factors are not limiting (*medium confidence*) (Quentin et al., 2015; Duan et al., 2018).

Forestry plantations are projected to be negatively impacted from increases in fire weather (Box 11.1), particularly in southern Australia (Pinkard et al., 2014) (*high confidence*). Increased pest damage due to temperature increases may reduce eucalypt and pine plantation growth by as much as 40% in some Australian environments by 2050) (Pinkard et al., 2014). Increased heat and water stress may enhance insect pest defoliation for *P. radiata* in Australia (e.g. *Sirex noctilio, Ips grandicollis and Essigella californica*) (Mead, 2013; Pinkard et al., 2014).

Combined impacts from heavy rainfall, soil erosion, drought, fire and pest incursions are projected to increase risks to the permanence of carbon offset and removal strategies in New Zealand for meeting its climate change targets (PCE, 2019; Watt et al., 2019; Anderegg et al., 2020; Schenuit et al., 2021). Effective management of the interactions between mitigation and adaptation policies can be achieved through governance and institutions, including Māori tribal organisations and sectoral adaptation, to ensure effective and continued carbon sequestration and storage as the climate changes (Lawrence et al., 2020b) (11.4.2) (Box 11.5) (*medium confidence*). The productivity of radiata pine (*P. radiata D. Don*) in New Zealand due to higher CO_2 is projected to increase by 19% by 2040 and 37% by 2090, but greater wind damage to trees is expected (Watt et al., 2019). Changes in the distribution of existing weeds, pests and diseases with potential establishment of new subtropical pests and seasonal invasions are projected (Kean et al., 2015; Watt et al., 2019; MfE, 2020a). Increased pathogens such as pitch canker, red needle cast and North American bark beetles could damage plantations (Hauraki Gulf Forum, 2017; Lantschner, 2017; Watt et al., 2019).

11.3.4.3.3 Adaptation

Adaptation options include: increased investment in monitoring forest condition and functioning; early detection and management of insect pests, diseases and invasive species; improved selection of land with appropriate growing conditions for plantation timber production under current and future conditions; trialling new species and genetic varieties; changing timing and frequency of planned fuel reduction fires, introducing more fire-tolerant tree species where appropriate, reducing ignition sources and maintaining access and emergency response capacity (Boulter, 2012; Pinkard et al., 2014; Keenan, 2017).

11.3.4.4 Marine Food

11.3.4.4.1 Observed impacts

Ecological impacts of climate change on fisheries species have already emerged (Morrongiello and Thresher, 2015; Gervais et al., 2021)(*high confidence*). This includes loss of habitats for fisheries species (Vergés et al., 2016; Babcock et al., 2019), and poleward shifts in distribution of barrens-forming urchins (Ling and Keane, 2018) impacting abalone and rock lobster fisheries. The percentage of reef as barrens across eastern Tasmania grew from 3.4% to 15.2% from 2001/02 to 2016/17, a ~10.5% increase per annum over the 15-year period (Ling and Keane, 2018). Oysters farmed from wild spat (Sydney rock oysters *Saccostrea glomerata*) are most at risk from climate change, primarily due to observed increases in summer temperatures and heat wave-related mortalities (Doubleday et al., 2013). The exceptional 2017/18 summer heatwave caused significant losses of farmed salmon in New Zealand, with farm owners seeking consent to move operations to cooler water (Salinger et al., 2019b).

11.3.4.4.2 Projected impacts

Aquaculture is projected to be more easily adapted than wild fisheries to avoid excessive exposure to the physio-chemical stresses from acidification, warming and extreme events (Richards et al., 2015). In New Zealand, wild and cultured shellfish are identified as most at risk from climate change (Capson and Guinotte, 2014). Changes in ocean temperature and acidification, and the downstream impacts on species distribution, productivity and catch are projected concerns (Law et al., 2016) (*medium confidence*) that impact Māori harvesting of traditional seafood, and the social, cultural and educational elements of food gathering (mahinga kai) (MfE, 2016). Warm temperate hatchery-based finfish species (yellowtail kingfish *Seriola lalandi*) are projected to be the least at risk, because of well controlled environmental conditions in hatcheries, and temperature increases which are expected to increase growth rates and productivity during the grow-out stage (Doubleday et al., 2013). For wild fisheries, multi-model projections suggest temperate and demersal systems, especially invertebrate shallow water species, would be more strongly affected by climate change than tropical and pelagic systems (Pecl et al., 2014; Fulton et al., 2018; Pethybridge et al., 2020) (*medium confidence*). In New Zealand waters, available habitat for both albacore tuna and oceanic tuna (Cummings et al., 2021) is expected to widen and shift.

11.3.4.4.3 Adaptation

Selective breeding in oysters is projected to be an important global adaptation strategy for sustainable shellfish aquaculture which can withstand future climate-driven change to habitat acidification (Fitzer et al., 2019). Less than a quarter of fisheries management plans for 99 of Australia's most important fisheries considered climate change, and only to a limited degree (Fogarty et al., 2019; Fogarty et al., 2021). Implementation of management and policy responses to climate change have lagged in part because climate change has not been considered as the most pressing issue (Hobday and Cvitanovic, 2017; Fogarty et al., 2019; Fogarty et al., 2021) (Cross-Chapter Box MOVING SPECIES in Chapter 5).

[START BOX 11.5 HERE]

Box 11.5: New Zealand's Land, Water and People Nexus under a changing climate

New Zealand's economy, dominated by the primary sector and the tourist industry (pre-COVID), relies upon a "clean green" image of water, natural ecosystems and pristine landscapes (Foote et al., 2015; Roche and Argent, 2015; Hayes and Lovelock, 2017). Water is highly valued by Māori for its mauri or life force and for its intrinsic values and multiple uses (Harmsworth et al., 2016). Increasingly, these diverse values are in conflict (Hopkins et al., 2015) due to increasing pressures from how land is used and managed and the effects on water availability and quality. Such tensions will be further challenged as temperatures rise and extreme events intensify beyond what has been experienced, thus stressing current adaptive capacities (Hughey and Becken, 2014; Cradock-Henry and McKusker, 2015; Hopkins et al., 2015; MfE and StatsNz, 2021) (11.2.2; 11.3.4) (*high confidence*).

Irrigation has increasingly been used to enhance primary sector productivity and regional economic development (Srinivasan et al., 2017; Fielke and Srinivasan, 2018; MfE and StatsNz, 2021). Pressure for long-term access to groundwater or large-scale water storage is increasing to ensure the ongoing viability of the primary sector as the climate changes. While investment in irrigation infrastructure may reduce climate change impacts in the short-term, maladaptive outcomes cannot be ruled out longer-term which means that focusing attention now on adaptive and transformational measures can help increase climate resilience in areas exposed to increasing drought and climate extremes that disrupt production (Abel et al., 2016; Cradock-Henry et al., 2019) (Yletyinen et al., 2019) (*medium confidence*).

Furthermore, over-allocation raises further tensions from competing uses of water such as for horticulture and urban water supplies, as well as for ecological requirements. The deterioration of water quality and loss of places of social, economic, cultural, and spiritual significance creates increasing tension for Māori especially (Harmsworth et al., 2016; Salmon, 2019; MfE and StatsNz, 2021). Public concern has increased about the deterioration of New Zealand's waterways and the profiting of some land uses at the expense of environmental quality and human health - tensions that make adaptation to climate change more challenging (Duncan, 2014; Foote et al., 2015; Scarsbrook and Melland, 2015; McDowell et al., 2016; McKergow et al., 2016; Greenhalgh and Samarasinghe, 2018). A lack of precautionary governance of water resources linked to unsustainable land use practices degrading water quality (Scarsbrook and Melland, 2015; Salmon, 2019) highlights the role that foresight could play in managing the nexus between land, water and people in a changing climate (11.3.3). Adaptive planning has potential for navigating these multi-dimensional challenges (Sharma-Wallace et al., 2018; Cradock-Henry and Fountain, 2019; Hurlbert et al., 2019) (11.7).

Furthermore, land and particularly plantation and native forests play a critical role in meeting New Zealand's emissions reduction goals. However, the persistence of land and forests as a carbon sink is uncertain and the sequestered carbon is at risk from future loss resulting from climate change impacts, including from increased fire, drought and pest incursions, storms and wind (IPCC, 2019a; PCE, 2019; Watt et al., 2019; Anderegg et al., 2020) (11.3.4.3), emphasising the importance of interactions between mitigation and adaptation policy and implementation. Integrated climate change policies across biodiversity, water quality, water availability, land use and forestry for mitigation can support the management of land use, water and people conflicts, but there is little evidence of such coordinated policies (Cradock-Henry et al., 2018b; Wreford et al., 2019). Implementation of the National Policy Statement for Freshwater Management 2020 (MfE, 2020b) and the National Adaptation Plan (due August 2022) present opportunities for such interconnections and diverse values to be addressed, as well as enabling sector and community benefits to be realised across New Zealand (Awatere et al., 2018; Lawrence et al., 2020b).

[END BOX 11.5 HERE]

11.3.5 Cities, Settlements and Infrastructure

Almost 90% of the population of Australia and New Zealand is urban (World Bank, 2019). Each country has vibrant and diverse urban, rural and remote settlements, with some highly disadvantaged areas isolated by distance and limited infrastructure and services (Argent et al., 2014; Charles-Edwards et al., 2018; Spector et al., 2019). Some areas in northern Australia and New Zealand, especially those with higher proportions of Indigenous inhabitants, face severe housing, health, education, employment and services issues (Kotey, 2015) which increases their vulnerability to climate change.

Infrastructure within and between cities and settlements is critical for activity across all sectors, with interdependencies increasing exposure to climate hazards (11.5.1). Previous planning horizons for existing infrastructure are compromised by now having to accommodate ongoing sea-level rise, warming, and increasing frequency of extreme rainfall and storm events (Climate Institute, 2012; MfE, 2017a). There is almost no information on the costs and benefits of adapting vulnerable and exposed infrastructure in Australia or New Zealand. Given the value of the infrastructure and the rising damage costs, this represents a large knowledge gap leading to an adaptation investment deficit.

11.3.5.1 Observed Impacts

Critical infrastructure, cities and settlements are being increasingly affected by chronic and acute climate hazards including heat, drought, fire, pluvial and fluvial flooding and sea-level rise, with consequent effects for many sectors (Instone et al., 2014; Loughnan et al., 2015; Zografos et al., 2016; Hughes et al., 2021) (*high confidence*). Risks and impacts vary with physical characteristics, location, connectivity and socio-economic status of settlements because of the ways these influence exposure and vulnerability (Loughnan et al., 2013; MfE, 2020a) (*high confidence*).

Weather-related disasters are causing significant disruption and damage (Paulik et al., 2019a; CSIRO, 2020; Paulik et al., 2020). In Australia, during 1987-2016, natural disasters caused an estimated 971 deaths and 4,370 injuries, 24,120 people were made homeless and about 9 million people were affected (Deloitte, 2017a). More than 50% of these deaths and injuries came from heatwaves in cities and 22% from fires. During 2007-2016, Australia natural disaster costs averaged A$18.2 billion per year with largest contributions from floods (A$8.8 billion), followed by cyclones (A$3.1 billion), hail (A$2.9 billion), storms (A$2.3 billion) and fires (A$1.1 billion) (Deloitte, 2017a). The Australian fires in 2019-2020 cost over A$8 billion, with devastating impacts on settlements and infrastructure (Box 11.1)

Sea-level rise affects many interdependent systems in cities and settlements which increase the potential for compounding and cascading impacts (11.5.1). Seaports, airports, water treatment plants, desalination plants, roads and railways are increasingly exposed to sea-level rise (*very high confidence*), impacting their longevity, levels of service and maintenance (*high confidence*) (McEvoy and Mullett, 2014; Woodroffe et al., 2014; PCE, 2015; Ranasinghe, 2016; Newton et al., 2018; Paulik et al., 2020) (Box 11.6). Compounding coastal hazards in New Zealand, such as elevated water tables associated with rising sea-level and intense rainfall (Morgan and Werner, 2015; McBride et al., 2016; White et al., 2017; Hughes et al., 2021) are exerting pressure on stormwater and wastewater infrastructure and drinking water supply and quality (MfE, 2020a).

Extreme heat events exacerbate problems for vulnerable people and infrastructure in urban Australia where urban heat is superimposed upon regional warming, and there are adverse impacts for population and vegetation health, particularly for socio-economically disadvantaged groups (Tapper et al., 2014; Heaviside et al., 2017; Filho et al., 2018; Gebert et al., 2018; Rogers et al., 2018; Longden, 2019; Marchionni et al., 2019; Tapper, In Press) (11.3.6), energy demand, energy supply and infrastructure (Newton et al., 2018) (11.3.10) (*very high confidence*). Extreme heat is increasingly threatening liveability in some rural areas in Australia (Turton, 2017), particularly given their reliance on outside physical work and older populations. Settlement design and the level of greening interact with climate change to influence local heating levels (Tapper et al., 2014; Wong et al., 2020; Tapper, In Press).

Floods cause major damage. The floods of early 2019 in north Queensland cost A$5.68 billion (Deloitte, 2019), while Cyclone Yasi and the Queensland floods of 2011 cost A$6.9 billion (Deloitte, 2016). Floodplains in New Zealand have considerably higher overall national exposure of buildings and population than coasts (Paulik et al., 2019a) (Box 11.4). The insured loss from the 12 costliest floods in New Zealand from 2007-2017 totalled NZ$471.56 million, of which NZ$140.48 million could be attributed to climate change (Frame et al., 2020).

Climatic extremes are exacerbating existing vulnerabilities *(high confidence)*. Long supply chains, poorly maintained infrastructure, social disadvantage and poor health, and lack of skilled workers (Eldridge and Beecham, 2018; Mathew et al., 2018; Rolfe et al., 2020) are contributing to serious stress and disruption (Smith and Lawrence, 2014; Kiem et al., 2016). In many rural settlements, population ageing and reliance on an over-stretched volunteer base for recovery from extreme events are increasing vulnerability to climate change (Astill and Miller, 2018; Davies et al., 2018). Recovery from long, intense, more frequent and compounding climatic events in rural areas has been disrupted by the erosion of natural, financial, built, human and social capital (De et al., 2016; Sheng and Xu, 2019). Delayed recovery from extreme climatic events has been compounded by long-term displacement which in turn prolongs the impacts (Matthews et al., 2019). Severe droughts have contributed to poor health outcomes for rural communities, including extreme stress and suicide (Beautrais, 2018; Perceval et al., 2019). In Australia, competition between water users has left some rural communities experiencing extreme water shortage and insecurity with associated health impacts (Wheeler et al., 2018; Judd, 2019) (Box 11.3).

11.3.5.2 Projected Impacts

Changes in heat waves, droughts, fire weather, heavy rainfall, storms and sea-level rise are projected to increase negative impacts for cities, settlements and infrastructure (Tables 11.3a and 11.3b; Boxes 11.1, 11.3, 11.4) (*high confidence*).

Increased floods, coastal inundation (assuming a sea-level rise of 1.6 m by 2100), wildfires, windstorms and heatwaves may cause property damage in Australia estimated at A$91 billion per year by 2050 and A$117 billion per year by 2100 for RCP8.5, while damage-related loss of property value is estimated at A$611 billion by 2050 and A$770 billion by 2100 for RCP8.5 (Steffen et al., 2019). For 1.0 m sea-level rise, the value of exposed assets in New Zealand would be NZ$25.5 billion (Box 11.6). For 1.1 m sea-level rise, the value of exposed assets in Australia would be A$164-226 billion (Box 11.6). These cost estimates exclude impacts on personal livelihood, well-being or lifestyle.

Extreme heat risks are projected to exacerbate existing heat-related impacts on human health, vegetation and infrastructure (Tapper et al., 2014; Tapper, In Press) (11.3.6). In Australia, the annual frequency of days over 35ºC is projected to increase 20-70% by 2030 (RCP4.5), and 25–85% (RCP2.6) to 80–350% (RCP8.5) by 2090 (Table 11.3a). For example, Perth may average 36 days over 35ºC by 2030 (RCP4.5). In New Zealand, the annual frequency of days over 25ºC may increase 20-60% (RCP2.6) to 50-100% (RCP8.5) by 2040, and 20–60% (RCP2.6) to 130-350% (RCP8.5) by 2090 (Table 11.3b). For example, Auckland may average 39 days over 25ºC by 2040 (RCP8.5). Unprecedented extreme temperatures, as high as 50ºC in Sydney or Melbourne, could occur with global warming of 2.0ºC (Lewis et al., 2017). Heat-related costs for Melbourne during 2012-2051 are estimated at A$1.9 billion, of which A$1.6 billion is human health/mortality costs (AECOM, 2012). Extreme heat is threatening liveability in some rural areas in Australia (Turton, 2017), particularly given their reliance on outside physical work and older populations.

Key infrastructure and services face major challenges. Structural metal corrosion rates are projected to increase significantly at coastal locations but decrease inland (Trivedi et al., 2014). A drier climate may decrease the rate of deterioration of road pavements but extreme rainfall events and heat pose a significant risk (Taylor and Philp, 2015), especially to unsealed roads in northern Australia (CoA, 2015). Critical infrastructure on coasts is at risk from sea-level rise and storm surges (Box 11.6). Facilities such as hospitals face weather-related hazards exacerbated by climate change and not originally anticipated in building and infrastructure design (Loosemore et al., 2011; Loosemore et al., 2014). By 2050, increased risks are projected for the availability and quality of potable water supplies, delivery of wastewater and stormwater services to communities, transport systems, electricity infrastructure, operating municipal landfills, and contaminated sites located near rivers and the coast (Gilpin et al., 2020; MfE, 2020a; Hughes et al., 2021). These then create risks to social cohesion and community wellbeing from displacement of individuals, families and communities, with inequitable outcomes for vulnerable groups (Boston and Lawrence, 2018).

11.3.5.3 Adaptation

In cities and settlements, climate adaptation is underway and is being led and facilitated by state and local government leadership and facilitation, particularly in Australia (Hintz et al., 2018; Newton et al., 2018) (Table 11.7, Supplementary Material Table SM11.1a) (*high confidence*).

Effective adaptations to urban heat include spatial planning, expanding tree canopy and greenery, shading, sprays and heat-resistant and energy-efficient building design, including cool materials and reflective or green roofs (*very high confidence*) (Broadbent et al., 2018; Jacobs et al., 2018b; Haddad et al., 2019; Haddad et al., 2020a; Yenneti et al., 2020; Bartesaghi-Koc et al., 2021; Tapper, In Press). Reducing urban heat not only benefits human health but reduces demand for, and cost of, air conditioning (Haddad et al., 2020b) and the risk of electricity blackouts (11.3.10).

Adaptation progress is being hampered by current urban redevelopment practice and statutory planning guidelines that are leading to removal of critical urban green space (Newton and Rogers, 2020). Reform of approaches to urban redevelopment would facilitate adaptation (Newton and Rogers, 2020). Several cities in Australia and New Zealand are part of the 100 Resilient Cities global network which helped facilitate the metropolitan Melbourne Urban Forest Strategy across councils (Fastenrath et al., 2019; Coenen et al., 2020) and in New Zealand, restoration of the urban forest in Hamilton is reducing heat stressors (Wallace and Clarkson, 2019). In peri-urban zones, adapting to fire risk is a contested issue, raising difficult trade-offs between heat management, ecological values and fuel reduction in treed landscapes (Robinson et al., 2018).

The resilience of Australia's major cities to flooding and drought has been advanced through a range of economic and physical interventions. Water sensitive urban design irrigates vegetation with harvested storm water that improves water security, flood risk, carbon sequestration, biodiversity, air and water quality, and delivers cooling that can save human lives in heatwaves (Wong et al., 2020). Storm water harvesting is supported by some councils in New Zealand and can deliver recycled water for households (Attwater and Derry, 2017), improving climate resilience and reducing water demand (White et al., 2017). Addressing infrastructure vulnerability is essential given the long lifetime of the assets, criticality of services and high costs of maintenance (Chester et al., 2020; Hughes et al., 2021).

Climate risk management is developing, but adaptive capacity, implementation, monitoring and evaluation are uneven across all scales of cities, settlements and infrastructure (*very high confidence*) (Tables 11.15a and 11.15b; Supplementary Material Tables SM11.1a, and SM11.1b). There is increasing awareness of the need to move from incremental coping and defensive coastal strategies (Jongejan et al., 2016) to transformational adaptation, for example, managed retreat (Torabi et al., 2018; Hanna, 2019), and to consider the flow-on effects (e.g. for housing and employment) (Fatorić et al., 2017; Torabi et al., 2018). Strategies limited to building household and community self-reliance (Astill and Miller, 2018) are increasingly inadequate given systemic and interconnected stressors and cascading impacts across interdependent systems (Lawrence et al., 2020b). Integrated approaches to climate change adaptation and emissions reduction have potential for addressing interdependent systems (e.g. nature-based approaches, climate-sensitive urban design, energy and transport systems) (Norman et al., 2021). Climate risk assessment and adaptation guidelines have been prepared for transport infrastructure authorities and organisations (Finlayson et al., 2017; Byett et al., 2019; Yenneti et al., 2020).

Table 11.7: Cities, settlements and infrastructure: key risks and adaptation options.

Sector	Key Risks	Adaptation Options	Inter-Sector Dependencies	Sources
Road	Heat; sea-level rise; coastal surges; floods and high intensity rainfall impacts on road foundations	Re-routing; coastal protection; improved drainage	Ports (fuel supply); rail (fuel supply); electricity	(NCCARF, 2013; CoA, 2018a; MfE, 2020a)
Rail	Extreme temperatures; flooding; sea-level rise; high intensity rainfall impacts on track foundations	Drainage and ventilation improvements; systematic risk assessments; overhead wire and rail/sleeper upgrades; rerouting	Electricity; telecommunications; fuel supply (transport, ports)	(CoA, 2018a; MfE, 2020a)
Urban and Rural Built Environment[1]	Extreme temperatures; floods; extreme weather events; wildfire (at urban-rural interface); sea-level rise	Multiple options from the building-to-city scale to reduce heat impacts and improve climate resilience; behavioural change; coastal defences and managed retreat	Road; rail; electricity; air and seaports; telecommunications; water and wastewater	(CoA, 2018a; Newton et al., 2018; Haddad et al., 2019; MfE, 2020a; Paulik et al., 2020; Tapper, In Press) (Box 11.4) (Box 11.4)

Electricity	High wind/ temperature events; wildfire; lightning; dust storms; drought (hydro)	Demand management; re-engineering and new technology; network intelligence; smart metering; improved planning for outages	Road; rail; water	(CoA, 2017; MfE, 2020a) (11.3.10.)
Ports: Air and Sea	Sea-level rise; coastal surges; wind; heat; extreme weather events	Air; improved coastal, pluvial and fluvial flood protection, on-site services. Sea; widening operational limits, raising wharfs, roads and breakwaters.	Electricity; road; rail, water	(McEvoy and Mullett, 2014; MfE, 2020a)
Telecommunications	Floods; wildfires; extreme wind	Protect; place underground; wireless systems	Electricity; digital connectivity; all sectors serviced; rural communities	(NCCARF, 2013)
Stormwater Wastewater and Water supply[1.]	High intensity rainfall; increased and extreme temperatures; flooding; drought; sea-level rise	Large investments in upgrading centralized infrastructure and capacity; increasing investment in decentralized infrastructure and capacity (e.g. Water Sensitive Urban Design); demand management; fewer options in smaller communities; governance at scale	Electricity; telecommunications; urban and rural built environment	(White et al., 2017; CoA, 2018a; Gilpin et al., 2020; MfE, 2020a; Wong et al., 2020; Hughes et al., 2021) (Box 11.4)

Table Notes:
[1.] Water supply safety and security and exposure of buildings have been identified as the most significant risks for New Zealand in terms of urgency and consequence (MfE, 2020a). No such ranking of risk has been done for Australia.

Infrastructure service vulnerability in New Zealand is supported by new institutional adaptations including the Infrastructure Commission to develop a 30-year national infrastructure strategy. The Climate Change Commission (Climate Change Commission, 2020) has issued six principles for climate-relevant infrastructure investments and is mandated to monitor the National Climate Change Adaptation Plan based on the first National Climate Change Risk Assessment (MfE, 2020a). A National Disaster Resilience Strategy addresses integrated planning for risk reduction and awareness-raising in New Zealand (Department of the Prime Minister and Cabinet, 2019).

Successive inquiries and reviews highlight potential synergies between disaster risk management and climate resilience (11.5.1) (Smith and Lawrence, 2018; Ruane, 2020). In Australia, there is a National Disaster Risk Reduction Framework (CoA, 2018b) and a National Recovery and Resilience Agency (CoA, 2021) that help underpin the development of national support systems for rural and regional emergency management and associated volunteer sectors (McLennan et al., 2016) and wildfire smoke impacts (CoA, 2020e). The National Heatwave Framework Working Group uses a Heatwave Forecast Service, and heatwave early warning and adaptation systems that operate in Adelaide, Melbourne, Sydney and Brisbane have reduced potential death rates (Nitschke et al., 2016).

Infrastructure planning is lagging behind international standards for climate resilience evaluation and guidance for adaptation to climate risk (CSIRO, 2020; Kool et al., 2020; Hughes et al., 2021) *(high* *confidence)*. Some companies have examined their exposure to climate risk and developed strategies to minimise their vulnerability (Climate Institute, 2012) (11.3.8). Climate risk assessments have been conducted for the electricity sector in both Australia and New Zealand (11.3.10). Climate change is considered in Australian infrastructure plans for national and regional water supply security, water for irrigated agriculture, a coastal hazards adaptation strategy, and the Tanami Road upgrade (Infrastructure Australia, 2016; Infrastructure Australia, 2019; Infrastructure Australia, 2021).

Industry associations are beginning to facilitate climate adaptation for infrastructure, including the Australian Green Infrastructure Council (CoA, 2015), the Green Building Council of Australia, Green Star Programme (GBCA, 2020), the Water Services Association of Australia, Climate Change Adaptation Guidelines (WSAA, 2016) and the Australian Sustainable Built Environment Council, Built Environment Adaptation Framework (ASBEC, 2012). The Infrastructure Sustainability Rating Scheme measures the social, environmental, governance and cultural outcomes delivered by more than $160 billion worth of infrastructure, and it is projected to deliver a cost-benefit ratio of 1:1.6 to 1:2.4 during 2020-2040 (RPS, 2020). There is scope for engagement of industry in transitioning to a low carbon green economy that is adapted to climate change, but less certainty on how to develop appropriate business cases (Newton and Newman, 2015).

There are tensions between settlement-scale adaptation options such as managed retreat that focus on the long term, and people's values, place attachments, needs and capacities (Gorddard et al., 2016; Fatorić et al., 2017; Graham et al., 2018; O'Donnell, 2019; Norman et al., 2021). Tensions also exist between climate change adaptation and mitigation goals (e.g. current energy efficiency standards in Australian buildings can worsen their heat resistance and increase dependence on air-conditioning) (Hatvani-Kovacs et al., 2018). Where there is a lack of coordination between jurisdictions, there can be flow-on effects from failure to adapt, for example in coastal local government areas (Dedekorkut-Howes et al., 2020) (Box 11.6). There is limited information across the region on climate change impacts and adaptation options for telecommunications (NCCARF, 2013) (Table 11.7). There is an emerging recognition that implementing and evaluating the adaptation process (vulnerability and risk assessments, identification of options, planning, implementation, monitoring, evaluation and review) in local contexts can advance more effective adaptation (Moloney and McClaren, 2018). For example, the Victorian State Government has built monitoring, evaluation and adaptation components into its adaptation plan (Table 11.15a).

[START BOX 11.6 HERE]

Box 11.6: Rising to the Sea-Level Challenge

Many of the region's cities and settlements, cultural sites and place attachments are situated around harbours, estuaries and lowland rivers (Black, 2010; PCE, 2015; Australia SoE, 2016; Rouse et al., 2017; Hanslow et al., 2018; Birkett-Rees et al., 2020) exposed to ongoing relative sea-level rise (RSLR). RSLR includes regional variability in oceanic conditions (Zhang et al., 2017) and vertical land movement along New Zealand's tectonically dynamic coasts (Levy et al., 2020) and some Australian hotspots for subsidence (Denys et al., 2020; King et al., 2020; Watson, 2020).

Table Box 11.6.1: Observed and projected impacts from higher mean sea level

Impacts from increase in mean sea level	References
Nuisance and extreme coastal flooding have increased from higher mean sea level in New Zealand. Projected sea level rise will cause more frequent flooding in Australia and New Zealand before mid-century (*very high confidence*)	(Hunter, 2012; McInnes et al., 2016; Stephens et al., 2017; Stephens et al., 2020) (Steffen et al., 2014; PCE, 2015; MfE, 2017a; Hague et al., 2019; Paulik et al., 2020)
Squeeze in intertidal habitats (*high confidence)*	(Steffen et al., 2014; Peirson et al., 2015; Mills et al., 2016a; Mills et al., 2016b; Pettit et al., 2016; Rouse et al., 2017; Rayner et al., 2021)

Significant property and infrastructure damage (*high confidence*)	(Steffen et al., 2014; PCE, 2015; Harvey, 2019; LGNZ, 2019; Paulik et al., 2020) (Table Box 11.5.2) (Table Box 11.6.2)
Loss of significant cultural and archaeological sites and projected to compound with several hazards over this century (*medium confidence*)	(Bickler et al., 2013; Birkett-Rees et al., 2020; NZ Archaeological Association, 2020)
Increasing flood risk and water insecurity with health and well-being impacts on Torres Strait Islanders (*high confidence*)	(Steffen et al., 2014; McInnes et al., 2016; McNamara et al., 2017)
Degradation and loss of freshwater wetlands (*high confidence*)	(Pettit et al., 2016; Bayliss and Ligtermoet, 2018; Tait and Pearce, 2019; Grieger et al., 2020; Swales et al., 2020)

Coastal shoreline position is driven by a complex combination of natural drivers, past and present human interventions, climate variability (Bryan et al., 2008; Helman and Tomlinson, 2018; Allis and Murray Hicks, 2019) and variation in sediment flux (Blue and Kench, 2017; Ford and Dickson, 2018). RSLR, to date, is a secondary factor influencing shoreline stability (*medium confidence*), and in Australia no definitive sea-level rise signature is yet observed in shoreline recession, nor documented in New Zealand, due to variability in shoreline position responding to storms and seasonal, annual and decadal climate drivers (Australian Government, 2009; McInnes et al., 2016; Sharples et al., 2020).

The primary impacts of rising mean sea level (Table Box 11.6.1) are being compounded by climate-related changes in waves, storm surge, rising water tables, river flows and alterations in sediment delivery to the coast (*medium confidence*). The net effect is projected to increase erosion on sedimentary coastlines and flooding in low-lying coastal areas(McInnes et al., 2016; MfE, 2017a; Hanslow et al., 2018; Wu et al., 2018). Waves are projected to be higher in southern Australasia and lower elsewhere (Morim et al., 2019) and storm surge slightly higher in the south, slightly lower further north in New Zealand (Cagigal et al., 2019) and small robust declines along southern Australia, with potentially larger changes in the Gulf of Carpentaria (Colberg et al., 2019).

The cumulative direct and residual risk from RSLR and associated impacts are projected to continue for centuries, necessitating on-going adaptive decisions for exposed coastal communities and assets (MfE, 2017c; Oppenheimer et al., 2019; Tonmoy et al., 2019) (*high confidence*).

Table Box 11.6.2: Observed relative sea-level rise (variance-weighted average) with uncertainty range (standard deviation) and projected impacts on infrastructure and population of 1.1 m in Australia and 1 m in New Zealand. Sea-level rise projections for 2050 and 2090 are given in Table 11.3a and Table 11.3b.

Country	Observed relative sea-level rise	Projected impacts of sea-level rise (1.1m Australia; 1.0m New Zealand)			
		Value of coastal urban infrastructure	Number of buildings exposed	Number of residents exposed	Public council assets exposed

Australia	2.2±1.8 mm/year to 2018 for four >75-year records (or an average of 0.17 m over 75 years). 3.4 mm/year from 1993-2019 (Watson, 2020)	A$164 to >226 billion (DCCEE, 2011; Steffen et al., 2019) 111% rise in inundation cost from 2020-2100 (Mallon et al., 2019)	187,000 to 274,000 residential buildings, 5,800 to 8,600 commercial buildings, 3,700 to 6,200 light industrial buildings (DCCEE, 2011)	N/A	27,000 to 35,000 km of roads, and 1,200 to 1,500 km of rail lines and tramways (DCCEE, 2011)
New Zealand	1.8 mm/year from 1900-2018, 1.2 mm/year from 1900-1960 and 2.4 mm/year from 1961-2018 (Bell and Hannah, 2019)	NZ$25.5 billion (Paulik et al., 2020)	75,890 (Paulik et al., 2020)	105,580 (Paulik et al., 2020)	4000 km pipelines, 1440 km roads, 101 km rail, 72 km electricity transmission lines (Paulik et al., 2020) NZ$5 billion (2018) (reserves, buildings, utility networks, roads) (LGNZ, 2019)

Prevailing decision-making assumes shorelines can continue to be maintained and protected from extreme storms, flooding and erosion, even with RSLR (Lawrence et al., 2019a). Rapid coastal development has increased exposure of coastal communities and infrastructure (*high confidence*) (Helman and Tomlinson, 2018; Paulik et al., 2020) reinforcing perceptions of safety (Gibbs, 2015; Lawrence et al., 2015) and creating barriers to retreat and nature-based adaptations (Schumacher, 2020) (*very high confidence*). The efficacy and increasing costs of protection and accommodation risk reduction approaches, and rebuilding after extreme events have been questioned and have limits (PCE, 2015; MfE, 2017a; Harvey, 2019; LGNZ, 2019; Paulik et al., 2020; Haasnoot et al., 2021). Future shoreline erosion is often signalled by using defined coastal setback lines(s) and using probabilistic approaches to signal uncertainty (Ramsay et al., 2012; Ranasinghe, 2016).

Flooding from high spring ("king") tides or storm tides during extreme weather events are raising public awareness of sea-level rise (Green Cross Australia, 2012) including through media coverage (Priestley et al., 2021). The use of adaptive decision tools (11.7.3.1; Table 11.17) is increasing the understanding of changing coastal risk (Bendall, 2018; Lawrence et al., 2019b; Palutikof et al., 2019b) and how dynamic adaptive pathways and monitoring of them can aid implementation (Stephens et al., 2018; Lawrence et al., 2020b). Collaborative governance between local governments and their communities, including with Māori tribal organisations, is emerging in New Zealand (OECD, 2019b) assisted by national direction (DoC NZ, 2010) and guidance on adaptive planning (Table 11.15b). This shift from reactive to pre-emptive planning is better suited to ongoing RSLR (Lawrence et al., 2020b).

In Australia, adaptation to sea-level rise remains uneven across jurisdictions in the absence of clear Federal or State guidance, rendering Australia unprepared for flooding from sea-level rise (Dedekorkut-Howes et al., 2020). Risk-averse coastal governance at the local level has led to shifts in liabilities to other actors and to future generations (Jozaei et al., 2020). Managed retreat has emerged as an adaptation option in New Zealand (Rouse et al., 2017; Hanna, 2019; Kool et al., 2020; Lawrence et al., 2020c) where protective measures are transitional (DoC NZ, 2010) and where managed retreat has arisen from collaborative governance (Owen et al., 2018). Remaining adaptation barriers are social or cultural (the absence of licence and legitimacy) and institutional (the absence of regulations, policies and processes that support changes to existing property rights and the funding of retreat) (O'Donnell and Gates, 2013; Tombs et al., 2018; Grace et al., 2019; O'Donnell et al., 2019) (*high confidence*).

Legacy development, competing public and private interests, trade-offs among development and conservation objectives, policy inconsistencies, short and long-term objectives, and the timing and scale of impacts, compound to create contestation over implementation of coastal adaptation (Mills et al., 2016b; McClure and Baker, 2018; Dedekorkut-Howes et al., 2020; McDonald, 2020; Schneider et al., 2020) (*high confidence*). Legal barriers to coastal adaptation remain (Schumacher, 2020) with a risk that the courts become decision makers (Iorns Magallanes et al., 2018) due to legislative fragmentation, status quo leadership, lack of coordination between governance levels and agreement about who pays for what adaptation (Waters et al., 2014; Boston and Lawrence, 2018; Palutikof et al., 2019a; Noy, 2020) (*very high confidence*). The nexus of climate, law, place and property rights continues to expose people and assets to ongoing sea-level rise (Johnston and France-Hudson, 2019; O'Donnell, 2019), especially where the risks of sea-level rise are not being reflected in property valuations (Cradduck et al., 2020). Risk signalling through land use planning, flooding events, and changes in insurance availability and costs, are projected to increase recognition of coastal risks (Storey and Noy, 2017; CCATWG, 2018; Lawrence et al., 2018a; Harvey and Clarke, 2019; Steffen et al., 2019; Cradduck et al., 2020; ICNZ, 2021) (*medium confidence*). Proactive local-led engagement and strategy are key to effective adaptation and incentivising and supporting communities to act(Gibbs, 2020; Schneider et al., 2020). Adopting 'fit for purpose' decision tools that are flexible as sea levels rise (11.7.3) can build adaptive capacity in communities and institutions (*high confidence*).

[END BOX 11.6 HERE]

11.3.6 Health and Wellbeing

11.3.6.1 Observed Impacts

There is ample evidence of health loss due to extreme weather in Australia and New Zealand, and rising temperatures, changing rainfall patterns and increasing fire weather have been attributed to anthropogenic climate change (11.2.1). Extreme heat leads to excess deaths and increased rates of many illnesses (Hales et al., 2000; Nitschke et al., 2011; Lu et al., 2020). Between 1991 and 2011 it is estimated that 35-36% of heat-related mortality in Brisbane, Sydney and Melbourne was attributable to climate change, amounting to about 106 deaths a year on average over the study period (Vicedo-Cabrera et al., 2021). Exposure to high temperatures at work is common in Australia, and the health consequences may include more accidents, acute heat stroke and chronic disease (Kjellstrom et al., 2016). Long-term rise in temperatures is changing the balance of summer and winter mortality in Australia (Hanigan et al., 2021). The Black Summer wildfires in Australia in 2019/2020 (Box 11.1) caused 33 deaths directly (Davey and Sarre, 2020) and exposed millions of people to heavy particulate pollution (Vardoulakis et al., 2020). In the Australian States most heavily affected by the fires, 417 deaths, 3151 hospital admissions for cardiovascular or respiratory conditions, and about 1300 emergency department presentations for asthma are attributed to wildfire smoke exposure (Borchers Arriagada et al., 2020). Immediate smoke-related health costs from the 2019-20 fires are estimated at A$1.95 billion (Johnston et al., 2020).

Extreme heat is associated with decreased mental well-being, more marked in women than men (Ding et al., 2016). Changing climatic patterns in Western Australia have undermined farmers' sense of identity and place, heightened anxiety and increased self-perceived risks of depression and suicide (Ellis and Albrecht, 2017). Following the Black Saturday wildfires in Victoria in 2009, 10-15% of the population in the most severely affected areas reported persistent fire-related post-traumatic stress disorder, depression and psychological distress (Bryant et al., 2014). Repeated exposure to the threat of wildfires in Australia, either directly (Box 11.1) or through media coverage (Looi et al., 2020) may compound effects on mental health. In March 2017, 31,000 people in New South Wales and Queensland were displaced by Tropical Cyclone Debbie. Six months post-cyclone, adverse mental health outcomes were more common among those whose access to health and social care was disrupted (King et al., 2020).

Dengue fever remains a threat in northern Australia and variations in rainfall and temperature are related to disease outbreaks and patterns of spread, although most outbreaks are sparked by travellers bringing the virus into the country (Bannister-Tyrrell et al., 2013; Hall et al., 2021). Cases of dengue fever and other arboviral diseases have been increasing amongst recent arrivals to New Zealand from overseas, but to date there have been no reports of local transmission (Ammar et al., 2021).

In 2016 in New Zealand, it is estimated 6-8,000 people became ill due to contamination of the Havelock North water supply with the bacteria *Campylobacter* (Gilpin et al., 2020). The infection was traced to sheep faeces washed into the underground aquifer that feeds the town's (untreated) water supply after an extraordinarily heavy rainfall event. This is not an isolated finding: increases in pediatric hospital admissions are seen across New Zealand two days after heavy rainfall events (Lai et al., 2020).

11.3.6.2 Projected impacts

Climate change is projected to have detrimental effects on human health due to heat stress, changing rainfall patterns including floods and drought, and climate-sensitive air pollution (including that caused by wildfires) (*high confidence*). Vulnerability to detrimental effects of climate change will vary with socio-economic conditions (*high confidence*).

The greatest number of people affected by compounding effects of heat, wildfires and poor air quality will be in urban and peri-urban areas of Australia. By 2100 the proportion of all deaths attributable to heat in Melbourne, Sydney and Brisbane may rise from about 0.5% to 0.8% (under RCP 2.6), or 3.2% (under RCP 8.5) (Gasparrini et al., 2017). Heat-wave related excess deaths in Melbourne, Sydney and Brisbane are projected to increase to 300/year (RCP2.6) or 600/year (RCP8.5) during 2031-2080 relative to 142/year during 1971-2020, assuming no adaptation and high population growth (Guo et al., 2018). High temperatures amplify the risks due to local air pollution: without adaptation, ozone-related deaths in Sydney may increase by 50-60 per year by 2070 (Physick et al., 2014).

Unless there is more effective control of nutrient run-off, bacterial contamination of drinking water supplies is projected to increase due to more intense rainfall events, exacerbating risks to human health (Gilpin et al., 2020, Lai, 2020 #2680), and higher temperatures will increase freshwater toxic blooms (Hamilton et al., 2016).

Less certain climate change impacts include: surges in vector-borne diseases (*medium confidence*); threats to mental health (*medium confidence*); reduction in winter mortality (*medium confidence*); emergence of new or poorly understood weather-related threats (such as thunderstorm asthma or interactions between rising heat and air pollution) (*low confidence*); and spill-over effects on health from global impacts of climate change (e.g., on trade, conflict, migration) (*low confidence*).

In general, the area of Australia suitable for transmission of dengue is projected to increase (Zhang and Beggs, 2018; Messina et al., 2019) but estimates of local disease risk vary considerably according to climate change scenario and socio-economic pathways (Williams et al., 2016). The spread of *Wolbachia* amongst *Aedes* mosquitoes in northern Australia has already reduced dengue transmission and may decrease the influence of climate in the future (Ryan et al., 2019). In New Zealand, the risk of dengue remains low for the remainder of this century (Messina et al., 2019). Higher temperatures and more intense rainfall may also increase pollen production and the risk of allergic illness throughout the region (Haberle et al., 2014).

11.3.6.3 Adaptation

Strengthening basic public health services can rapidly reduce vulnerability to death and ill-health caused by climate change, however this opportunity is often missed (*very high confidence*). The 2020 New Zealand Health and Disability System Review pointed to short-comings in leadership and governance, structures that embed health inequity, lack of transparency in planning and reporting, and under-investment in public health personnel and systems (HDSR, 2020). An Australian study found that without deliberate planning the health system 'would only be able to deal with climate change in an expensive, *ad hoc* crisis management manner' (Burton, 2014). In both Australia and New Zealand the COVID-19 epidemic has highlighted weaknesses in information systems, primary care for marginalized groups and inter-sectoral planning (Salvador-Carulla et al., 2020; Skegg and Hill, 2021): all these deficiencies are relevant to climate adaptation.

Underlying health and economic trends affect the vulnerability of the population to extreme weather (*high confidence*). Poor housing quality is a risk factor for climate-related health threats (Alam et al., 2016). Homeless people lack access to temperature-controlled or structurally safe housing, and often are excluded from disaster preparation and responses (Every, 2016). These inequalities are reversible. For example, a government partnership with social housing providers in Australia improved the thermal performance of housing for low-income tenants (Barnett et al., 2014a). A postcode-level analysis of the vulnerability of urban populations to extreme heat in Australian capital cities (Loughnan et al., 2013) led to the development of an interactive website for purposes of planning and emergency preparedness (Figure 11.5) as well as subsequent work on green urban design for cooler, more liveable cities (Tapper, In Press).

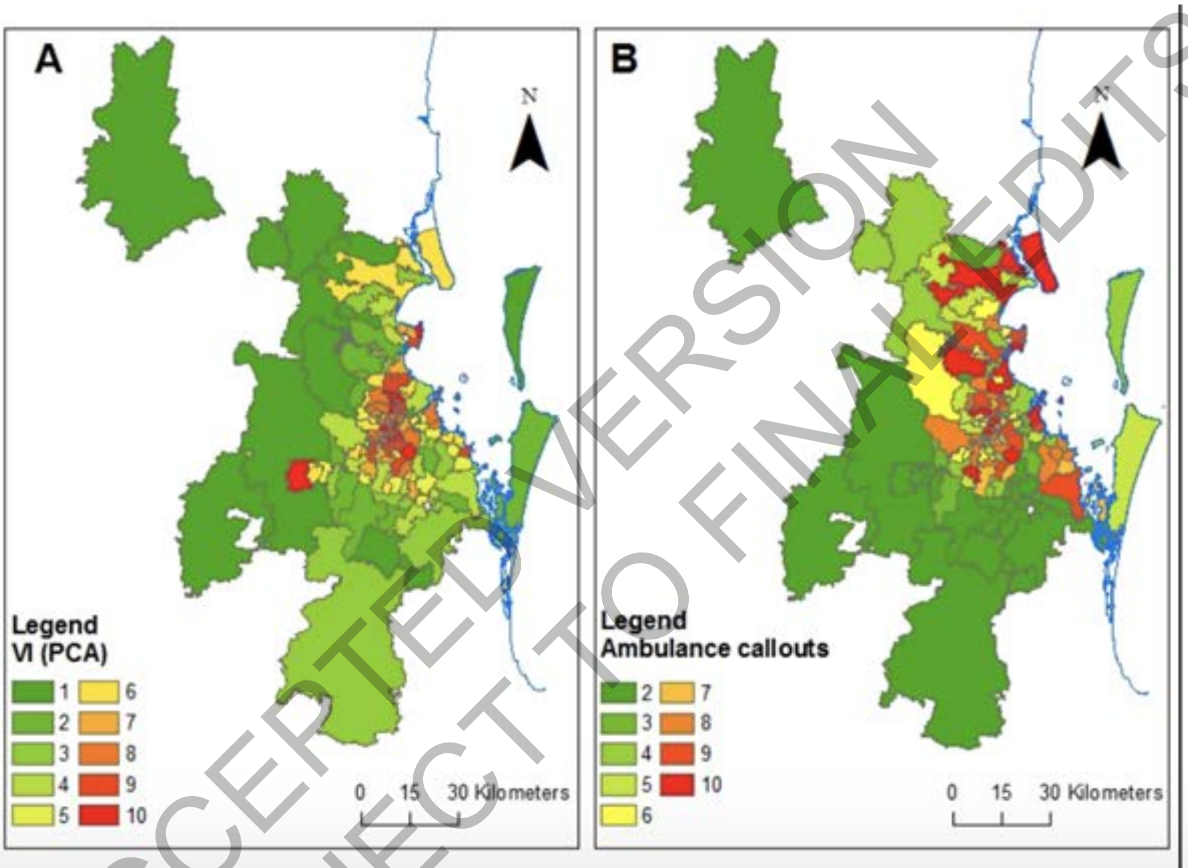

Figure 11.5: Housing and socio-economic disadvantage is correlated with the use of emergency services on hot days (rho = 0.55, $p<0.01$). The spatial distribution of (A) a community vulnerability index (VI (PCA) by deciles and (B) ambulance call-outs on days above daily mean of 34ºC, in Brisbane, Australia. Ambulance call-out data are expressed as deciles based on per-capita calls during 2003-2011 (Loughnan et al., 2013).

Heat-wave responses, from public education to formal heat-warning systems, are the best-developed element of adaptation planning for health in Australia, but many metropolitan centres are still not covered (Nicholls et al., 2016; Nitschke et al., 2016) (*high confidence*). Air conditioning (AC) in Australian homes reduces mortality in heat-waves by up to 80% (Broome and Smith, 2012) but heavy reliance on AC carries risks. It is estimated that a power outage on the third day of extreme heat-waves would result in an additional 10–21 deaths in Adelaide, 24–47 in Melbourne and 7–13 in Brisbane (Nairn and Williams, 2019). Multiple interventions at the landscape, building and individual scale are available to reduce the negative health effects of extreme heat (Jay et al., 2021)

Heat extremes receive most policy attention, but the numbers of deaths are less than those resulting from more frequent exposures to moderately high temperatures (Longden, 2019). Melbourne provides a case study in long-term planning for cooler cities, with its Urban Forest Strategy (Gulsrud et al., 2018). Australian workers' perceptions of heat and responses to high temperatures show that heat policies on their own are insufficient for full protection; workers also require knowledge and agency to slow down or take breaks on their own initiative (Singh et al., 2015; Lao et al., 2016).

The first national climate change risk assessment in New Zealand (MfE, 2020a) highlighted the risk to potable water supplies. An inquiry into the Havelock North outbreak recommended that all registered drinking water supplies (which supply about 80% of the national population) in New Zealand should be disinfected and have stronger oversight by a national regulatory body (Government Inquiry into Havelock North Drinking Water, 2017). The use of local and Indigenous knowledge strengthens interventions to protect water supplies to remote settlements that may be affected by climatic changes (Henwood, 2019).

Adaptation requires better protection of health facilities and supply chains, but hospital managers seldom have capacity to invest in long-term improvements in infrastructure (Loosemore et al., 2014). However, health services in the region are required to prepare disaster plans: these could be expanded to explicitly cover health adaptation and local threats from climate change, including flooding events (Rychetnik et al., 2019).

11.3.7 Tourism

11.3.7.1 Observed Impacts

Tourism is a major economic driver in the region, accounting for 3% (Australia) and 6% (New Zealand) of GDP pre-COVID-19 (WTTC, 2018). Climate change is having significant impacts on tourism due to the heavy reliance of the sector on natural heritage and outdoor attractions (11.3.1; Box 11.2). Furthermore, as Australia and New Zealand are both long-haul destinations, a global increase in 'flygskam' (flight shame) will to impact travel patterns (Becken et al., 2021).

Impacts of climate change are being observed across the tourism system (Scott et al., 2019a) (*high confidence*), most notably the Great Barrier Reef (Box 11.2) (Ma and Kirilenko, 2019). Australia's ski industry is very sensitive to climatic change, due to reduction in snow depth and the length of the snow season (Table 11.2) (Steiger et al., 2019; Knowles and Scott, 2020). The 2019-2020 summer wildfires (Box 11.1), impacted tourism and travel infrastructure, affecting air quality, vineyards and wineries (CoA, 2020e; Filkov et al., 2020). Global media coverage of the wildfires, alongside Australia's climate change policy response, profoundly and negatively, affected Australia's destination image (Schweinsberg et al., 2020; Wen et al., 2020). In New Zealand's South Island, Fox and Franz Josef Glaciers have retreated approximately 700m since 2008, with ice melt and retreat resulting in increased rock fall risks and negatively affecting the tourist experience (Purdie, 2013; Stewart et al., 2016; Wang and Zhou, 2019). The West Coast of New Zealand is extremely prone to flooding events impacting amenity values and access (Paulik et al., 2019b). Damage to tracks, huts and bridges have closed popular destinations, including the Hooker Glacier and the popular Routeburn and Heaphy Tracks during heavy rainfall events (Christie et al., 2020). Climate-driven damage is motivating 'last chance' tourism to see key natural heritage and outdoor attractions, e.g. Great Barrier Reef (Piggott-McKellar and McNamara, 2016) and Franz and Fox Glaciers (Stewart et al., 2016).

11.3.7.2 Projected Impacts

Widespread impacts from projected climate change are *very likely* across the tourism sector. The World Heritage listed Kakadu National Park in Australia is projected to experience increasing severity of cyclones (Turton, 2014) and sea-level rise is projected to affect freshwater wetlands (11.3.1.2; Table 11.5) (McInnes et al., 2015) and Indigenous rock art (Higham et al., 2016; Hughes et al., 2018a). The projected increase in the number of hot days in northern and inland Australia may impact the attractiveness of the region for tourists (Amelung and Nicholls, 2014; Webb and Hennessy, 2015). Coastal erosion and flooding of Australasian beaches due to sea-level rise and intensifying storm activity is estimated to increase by 60% on the Sunshine Coast by 2030 causing significant damage to tourist-related infrastructure (Hughes et al., 2018a). Urgent 'hard' and 'soft' adaptation strategies are projected to help reduce sea-level rise impacts (Becken and Wilson, 2016).

Glacier tourism, a multimillion-dollar industry in New Zealand, is potentially under threat because glacier volumes are projected to decrease (Purdie, 2013) (*very high confidence).* Glacier volume reductions of 50–92% by 2099 relative to present reflect the large range of temperature projections between RCP2.6 and RCP8.5. Under RCP2.6 at 2099, the glaciers retain a similar configuration to present, although clean-ice glaciers will retreat significantly. For RCP4.5, RCP6.0 and RCP8.5, the clean-ice glaciers will retreat to become small remnants in the high mountains (Anderson et al. 2021).

Snow skiing faces significant challenges from climate change (*high confidence*). In Australia, the annual maximum snow depth is estimated to decrease from current levels by 15% (2030) and 60% by 2070 (SRES A2) (Di Luca et al., 2018). By 2070-2099, relative to 2000-2010, the length of the Victorian ski-season is projected to contract by 65-90% under RCP8.5 (Harris et al., 2016). The New Zealand tourism destination of Queenstown is expected to experience declining snowfall, increased wind and more severe weather events (Becken and Wilson, 2016). Ski tourism stakeholders have been responding to longer-term climate risks with an increase in snow-making machines in New Zealand since 2013 (Hopkins, 2015) and in Australia (Harris et al., 2016).

11.3.7.3 Adaptation

Current snow-making technologies are expected to sustain the ski industry until mid-century. However, with warmer winter temperatures and declining water availability, snow-making is projected to decrease to half at most resorts by 2030 (Harris et al., 2016). New Zealand's ski industry may benefit from Australian skiers visiting New Zealand, due to lower relative vulnerability (Hopkins, 2015). However, tourists may substitute destinations or ski less in the absence of snow (*medium agreement, limited evidence*) (Cocolas et al., 2015; Walters and Ruhanen, 2015).

With the exception of the ski industry (Becken, 2013; Hopkins, 2015), tourism stakeholders generally focus on coping with short-term weather events, rather than longer-term climate risks, but do exhibit high adaptive capacity by diversifying their activities (Stewart et al., 2016). Post Covid-19 pandemic economics and recovery policies challenge this sector's prospects, and the combination of COVID-19 and climate change (e.g. fires, floods) has also highlighted the need for the tourism sector to be able to respond to multiple, overlapping crises.

There is limited evidence that research into the impact of climate change on tourism in Australia and New Zealand is translating into policy or action (Moyle et al., 2017). New Zealand government tourism sector strategies acknowledge this and the need for greater understanding of climate change for the sector, (TIA, 2019), but do not offer solutions (MBIE, 2019b; MfE, 2020a). The COVID-19 pandemic and the global pause of international travel offers an opportunity to potentially 'reset' tourism to account for the impacts of climate change (Prideaux et al., 2020).

11.3.8 Finance

11.3.8.1 Observed Impacts

The finance sector has significant exposure to climate variability and extreme events (*high confidence*). Aggregated insured losses from weather-related hazard events from 2013-2020 were almost A$15 billion for Australia (1.2% of GDP) and almost NZ$1 billion for New Zealand (0.4% of GDP) (ICA, 2020a; NIWA, 2020). However, there is no trend in normalised losses because the rising insurance costs are being driven by more people living in vulnerable locations with more to lose (McAneney et al., 2019). In New Zealand, two major hailstorms during 2014-2020 and three major floods during 2019-2021 caused significant insurance losses (ICNZ, 2021). Insured losses exceeded NZ$472 million for the 12 costliest floods from 2007-2017, of which NZ$140 million could be attributed to anthropogenic climate change (Frame et al., 2020). In Australia, insured damage was almost A$1.0 billion for the Queensland hailstorm in 2020, A$1.7 billion for east coast flooding in 2020, A$2.3 billion for the 2019-2020 fires, A$2.3 billion for the Queensland hailstorm in 2019, A$1.2 billion for the north Queensland floods in 2019, A$1.4 billion for the NSW hailstorm in 2018, A$1.8 billion for Cyclone Debbie in 2017 and A$1.5 billion for the Brisbane hailstorm in 2014 (ICA, 2020b). The insured loss from the seven costliest hailstorms in Australia from 2014-2021 totalled A$7.6 billion (ICA, 2021).

Some homes in the highest risk areas tend to be in lower socio-economic groups that may not buy insurance (Actuaries Institute, 2020). For example, one quarter of residents that experienced loss or damage in the 2019 Townsville floods did not have insurance (ACCC, 2020). Under-insurance reduces people's capacity to recover from adverse events, while over-reliance on private insurance undermines collective disaster recovery efforts (Lucas and Booth, 2020). In Australia, those in high-risk areas minimise house and contents insurance for financial reasons (Booth and Harwood, 2016; Osbaldison et al., 2019; Actuaries Institute, 2020). Insurance premiums in northern Australia are almost double those in the rest of Australia, and rising, mainly due to cyclone damage (ACCC, 2020).

11.3.8.2 Projected Impacts

Risks for the finance sector are projected to increase (*medium confidence*). The potential impact of increased coastal and inland flooding, soil desiccation and contraction, fire and wind could lead to higher insurance costs, reduced property values and difficulty for some customers to service loans (CBA, 2018). Under a high emission scenario (RCP8.5), estimated annual losses to home-lending customers may increase 27% by 2060, and the proportion of properties with high credit risk may rise from 0.01% in 2020 to 1% in 2060, assuming no change in the portfolio (CBA, 2018). In New Zealand, weather-related insurance claims between 2000–2017 totaled NZ$450 million, 40% of which were due to extreme rainfall. Using six climate model projections of extreme rainfall, the insured damage is projected to increase by 7% (RCP2.6) to 8% (RCP8.5) by 2020–2040 and 9% (RCP2.6) to 25% (RCP8.5) by 2080–2100, relative to 2000–2017 (Pastor-Paz et al., 2020). By 2050–2070, tropical cyclone risk for properties not in flood plains or storm surge zones in south-east Queensland may increase by 33% under a 2°C scenario, and by 317% under a 3°C scenario for properties in flood plains and storm surge zones (IAG, 2019).

11.3.8.3 Adaptation

Banks, insurers and investors increasingly recognise the risks posed by climate change to their businesses (Paddam and Wong, 2017) (*high confidence*). Collaborations between banks, insurers and superannuation funds in Australia and New Zealand are driving efforts aimed at achieving the Paris Agreement goals, including the New Zealand Centre for Sustainable Finance and Australian Sustainable Finance Initiative (AFSI, 2020; TAO, 2020; NZCFSF, 2021). Company directors including superannuation fund directors have legal obligations to disclose and appropriately manage material financial risks (Barker et al., 2016; Hutley and Davis, 2019). Financial regulators are aware of climate risks for financial stability and financial institutions (RBNZ, 2018; RBA, 2019) and are closely supervising climate risk disclosure practices (TCFD, 2017; RBNZ, 2018; APRA, 2019; CMSI, 2020; IGCC, 2021b). In Australia, regulatory action (APRA, 2021) includes issuing prudential guidelines for financial institutions on managing climate risk, aligned with guidelines developed by the Climate Measurement Standards Initiative (NESP ESCC, 2020). In New Zealand, the Financial Sector (Climate-related Disclosure and Other Matters) Amendment Bill aims to ensure that the effects of climate change are routinely considered in business, investment, lending, and insurance underwriting decisions (NZ Government, 2021).

Banks and insurers are beginning to undertake climate risk analyses (CRO Forum, 2019; Bruyère et al., 2020) and disclose their risks (Paddam and Wong, 2017; ANZ, 2018; CBA, 2018). For example, the agricultural banking sector has analysed climate risk and embedded climate adaptation financing into its risk scoring and lending practices (CBA, 2019). However, the overall number of disclosures continues to lag expectations, suggesting the need for mandatory climate risk disclosure in Australia (IGCC, 2021a).

Climate adaptation finance is not evident (*medium confidence*). There is an adaptation finance gap (Mortimer et al. 2020). Private sector initiatives are beginning to emerge through large scale projects or public-private partnerships, such as the Queensland Betterment Fund (Banhalmi-Zakar et al., 2016; Ware and Banhalmi-Zakar, 2020). Addressing investor pressure (IGCC, 2017) could increase investment in adaptation. However, ongoing policy uncertainty in Australia continues to be the key barrier to allocating further capital to invest in climate solutions for 70% of investors (IGCC, 2021a).

Current and future insurance affordability pressures could be addressed by increased mitigation, revisions to building codes and standards, and better land-use planning (ACCC, 2020; Actuaries Institute, 2020). In New Zealand, insurance signals are motivating the government to address adaptation funding mechanisms (Boston and Lawrence, 2018; CCATWG, 2018). Some insurers offer premium discounts to customers with reduced risk (Drill et al., 2016) with increasing premiums reflecting known risk and no cover for some hazards in risky locations (CCATWG, 2017). Special excess payments are available for flood hazard so customers take responsibility for part of the claim, with increasing premiums to reflect known and foreseeable risk, and downgrading cover from replacement value to market value (Bruyère et al., 2020). Retreat by private insurers from risky locations could increase the unfunded fiscal risk to the government (Storey and Noy, 2017) creating moral hazard (Boston and Lawrence, 2018). The litigation risk from failing to take adaptation action (Hodder, 2019) could affect financial markets and government policy settings, creating cascading impacts across society (Lawrence et al., 2020b)(CRO Forum, 2019). For some climate risks, national governments act as "last resort" insurers (CCATWG, 2017), but this could become unsustainable (CRO Forum, 2019).

11.3.9 Mining

Many mines are exposed and sensitive to climate extremes (*high confidence*), but there is little available research on climate change impacts (Odell et al., 2018). Most Australian mines face higher temperatures, cyclones, erosion and landslides, and hazards such as sea-level rise and storms across their supply chains, including ports (Cahoon et al., 2016). Impacts include operational disruptions such as acute drainage problems (Loechel and Hodgkinson, 2014) and heat-induced illness, irritation and absenteeism among workers (McTernan et al., 2016), lost revenue and increased costs (Pizarro et al., 2017).

Damage and disruption from climate impacts can cost operators billions of dollars (Cahoon et al., 2016). Climatic extremes increase the risk and impact of spillages along transportation routes (Grech et al., 2016) exacerbate mining's effects on hydrology, ecosystems, and air quality (Phillips, 2016; Ali et al., 2018); increase contamination risks (Metcalfe and Bui, 2016); and disrupt and slow mine site rehabilitation (Wardell-Johnson et al., 2015; Hancock et al., 2017). Adaptations such as improved water management are emerging slowly (Gasbarro et al., 2016; Becker et al., 2018). Some companies are spatially diversifying and relocating (Hodgkinson et al., 2014). Others are replacing workers with automation and remote operations (Halteh et al., 2018; Keenan et al., 2019).

11.3.10 Energy

Australia's energy generation is a mix of coal (56%), gas (23%) and renewables (21%) (DISER, 2020), with ageing coal-fired infrastructure being replaced with a growing proportion of renewable and distributed energy resources (AEMO, 2018). In New Zealand, 60% of energy generation comes from hydro-electricity and 15% from geothermal (MBIE, 2021), with coal (2%) and gas (13%) generation capacity to be retired, and total renewable energy to increase from 82% in 2017 to around 95% by 2050, mostly through wind generation (MBIE, 2019a).

11.3.10.1 Observed Impacts

The energy sector is highly vulnerable to climate change (*high confidence*). Oil and gas systems are vulnerable to storms, fires, drought, floods, sea-level rise, extreme heat and fires which can damage infrastructure, slow production, and add to operational costs (Smith, 2013). The electricity system is vulnerable to high temperatures reducing generator and network capacity and increasing failure rates and maintenance costs(AEMO, 2020a). Fires (including those sparked by electrical distribution lines) pose risks to assets, smoke can cause electricity transmission to trip, high winds reduce wind-energy capacity and threaten the integrity of transmission lines, low rainfall reduces hydro-energy capacity and increases the demand for desalination energy, higher sea-level may affect some low-lying generation, distribution and transmission assets, and compound extreme weather events can cause outages (Vose and Applequist, 2014; Lawrence et al., 2016; AEMO, 2020b; AEMO, 2020a; ESCI, 2021). For example, in September 2016, a major windstorm in South Australia damaged 23 transmission towers and cut power to over 900,000 households. In February 2017, the South Australian energy system failed to cope with a heatwave-related jump in demand, causing power cuts to 40,000 homes (Steffen et al., 2017). In April 2018, a storm over

Auckland New Zealand left 182,000 properties without power (Bell, 2018). The 2019/20 Australian heatwaves and fires caused widespread blackouts that disrupted communications, transport, and emergency response capacity (Box 11.1).

11.3.10.2 Projected Impacts

Risks for the energy sector are projected to increase with climate change (*medium confidence*). Projected increases in the frequency and intensity of heatwaves, fires, droughts and wind-storms would increase risks for energy supply and demand (AEMO, 2020b; ESCI, 2021). Households are unevenly vulnerable to energy sector risks due to varying housing quality and health dependencies (11.3.6). In New Zealand, a warmer climate and increasing energy efficiency is projected to marginally reduce annual average peak electricity heating demand (Stroombergen et al., 2006; MBIE, 2019a). Winter and spring inflows to main hydro lakes are projected to increase 5-10% and may reduce hydroelectric energy vulnerability (McKerchar and Mullan, 2004; Poyck et al., 2011; Stevenson et al., 2018). However, major electricity supply disruptions are projected to increase as dependence on electricity grows from 25% of total energy in 2016 to 58% in 2050 (Transpower, 2020).

In Australia, the total heating and cooling energy demand of 5-star energy-rated houses is projected to change by 2100 (Wang et al., 2010). At 2°C global warming, the estimated change in demand is –27% in Hobart, –21% in Melbourne, +61% in Darwin, +67% in Alice Springs and +112% in Sydney. For a 4°C global warming, the changes are –48%, –14%, +135%, +213% and +350% respectively.

11.3.10.3 Adaptation

Options to manage risks include adaptation of energy markets, integrated planning, improved asset design standards, smart-grid technologies, energy generation diversification, distributed generation (e.g. roof-top solar, micro-grids), energy efficiency, demand management, pumped hydro storage, battery storage, and improved capacity to respond to supply deficits and balance variable energy resources across the network (Table 11.8) (*high confidence*). With increasing electrification, diversification and resilience can contribute to security of supply as fossil fuels are retired from the energy mix (AEMO, 2020b). In Australia, the AEMO (2020) Integrated System Plan has evaluated various options, costs and benefits. Risks associated with an increasing reliance on weather-dependent renewable energy (e.g. solar, wind, hydro) (ESCI, 2021) can be managed through strong long-distance interconnection via high voltage powerlines and storage (Blakers et al., 2017; Blakers et al., 2021; Lu et al., 2021). However, implementation of adaptation options remains inadequate (Gasbarro et al., 2016).

Table 11.8: Adaptation options for the energy sector.

Adaptation options	References
Diversification of electricity supplies geographically and technically, including distributed energy resources and variable renewable energy	(AEMO, 2020b)
Integrated planning, improved asset design and management, and disaster recovery to build resilience to more extreme weather	(AEMO, 2020b; Transpower, 2020)
Augmentation of transmission grid to support change in generation mix using interconnectors and renewable energy zones, coupled with energy storage, adds capacity and helps balance variable resources across the network	(Blakers et al., 2017; ICCC, 2019; AEMO, 2020b)
Climate change risks included in the design, location, and rating of future infrastructure and consideration of the implications for future transmission developments	(Bridge et al., 2018; AEMO, 2020b)
Increased design and construction standards, flood defence measures, insurance, improved water efficiency, improved insulation of super-cooled LNG processes, more efficient air conditioning and creating fire breaks for the oil and gas sector	(Smith, 2013; Gasbarro et al., 2016)

Technological developments to strengthen existing resilience under climate change that reinforces the relative advantage of Western Australia and Tasmania for new wind energy installations	(Evans et al., 2018)
Energy generation diversity, demand management, pumped hydro storage and battery storage	(Keck et al., 2019; Transpower, 2020)
Tools and strategies to manage winter energy deficits and dry years alongside renewable electricity generation deployment	(Transpower, 2020)
Improved insulation and heating of buildings, and flexible electricity consumption to reduce the significance of winter electricity demand peak	(Stroombergen et al., 2006; MBIE, 2019a; Transpower, 2020)

11.3.11 Detection and Attribution of Observed Climate Impacts

Detection and attribution of observed climate trends and events is called 'climate attribution'. This has been assessed by IPCC Working Group I (Gutiérrez et al., 2021; Ranasinghe et al., 2021; Seneviratne et al., 2021) and summarised in IPCC Working Group 2 Chapter 16. Trends that have been formally attributed in part to anthropogenic climate change include regional warming trends and sea-level rise, decreasing rainfall and increasing fire risk in southern Australia. Events include extreme rainfall in New Zealand during 2007-2017, the 2007/8 and 2012/13 droughts in New Zealand, high temperatures in Australia during 2013-2020, the 2016 northern Australian marine heatwave, the 2016/2017 and 2017/18 Tasman Sea marine heatwaves, and 2019/2020 fires in Australia.

Detection and attribution of climate impacts on natural and human systems is called 'impact attribution'. This often involves a two-step approach (joint attribution) that links climate attribution to observed impacts. Impact attribution is complicated by confounding factors, e.g. changes in exposure arising from population growth, urban development and underlying vulnerabilities.

Impact attribution has been considered in Sections 11.3.1 to 11.3.10 and summarised in Table 11.9. More literature is available for natural systems than human systems, which represents a knowledge gap rather than an absence of impacts that are attributable to anthropogenic climate change. Fundamental shifts in the structure and composition of some ecosystems are partly due to anthropogenic climate change (*high confidence*). In human systems, the costs of droughts and floods in New Zealand, and heat-related mortality and fire damage in Australia, are partly attributed to anthropogenic climate change (*medium confidence*).

Table 11.9: Examples of observed impacts that can be partly attributed to climate change.

Impact	Source
Mass bleaching of the Great Barrier Reef in 2016/2017 due to a marine heatwave	Box 11.2
In the New Zealand Southern Alps, extreme glacier mass loss was at least six times more likely in 2011, and ten times more likely in 2018, due to warming	11.2.1, 11.3.3
In the Australian Alps bioregion, loss of habitat for endemic and obligate species due to snow loss and increases in fire, drought and temperature	Table 11.4
In the Australian wet tropics world heritage area, some vertebrate species have declined in distribution area and population size due to increasing temperatures and length of dry season	Table 11.4
Extinction of Bramble Cay melomys due to loss of habitat caused by storm surges and sea-level rise in Torres Strait	Table 11.4
In New Zealand, increasing invasive predation pressure on endemic forest birds surviving in cool forest refugia due to anthropogenic warming	Table 11.4
In New Zealand, erosion of coastal habitats due to more severe storms and sea-level rise	Table 11.4, Box 11.6

In Australia, estuaries warming and freshening with decreasing pH	Table 11.6
Changes in life-history traits, behaviour or recruitment of fish and invertebrates due to ocean acidification or warming, severe decline in recruitment of coral on the Great Barrier Reef due to ocean warming, aquaculture stock deaths due to heat stress	Table 11.6
New diseases and toxins due to warming and extension of East Australian Current	Table 11.6
Changes in almost 200 marine species distributions and abundance due to ocean warming	Table 11.6
Temperate marine species replaced by seaweeds, invertebrates, corals and fishes characteristic of subtropical and tropical waters	Table 11.6
River flow decline in southern Australia is largely due to the decline in cool season rainfall partly attributed to anthropogenic climate change	11.3.3
In New Zealand, the 2007/08 drought and the 2012/13 drought were 20% attributed to anthropogenic climate change	11.3.3
In New Zealand, about 30% of the insured damage for the 12 costliest flood events from 2007-2017 can be attributed to anthropogenic climate change	11.3.8
In Australia, 35-36% of heat-related excess mortality in Melbourne, Sydney and Brisbane from 1991-2018 can be attributed to anthropogenic climate change	11.3.6

11.4 Indigenous Peoples

Indigenous perspectives of well-being embrace physical, social, emotional and cultural domains, collectiveness and reciprocity, and more fundamentally connections between all elements across the past, present and future generations (Australia. NAHS Working Party, 1989; MfE, 2020a). Changing climate conditions are expected to exacerbate many of the social, economic and health inequalities faced by Aboriginal and Torres Strait Islander Peoples in Australia and Māori in New Zealand (Bennett et al., 2014; Hopkins et al., 2015; AIHW, 2016; Lyons et al., 2019) (*high confidence*). As a consequence, effective policy responses are those that take advantage of the interlinkages and dependencies between mitigation, adaptation and Indigenous Peoples' wellbeing (Jones, 2019) and those that address the transformative change needed from colonial legacies (Hill et al., 2020) (*high confidence)*. There is a central role for Indigenous Peoples in climate change decision making that helps address the enduring legacy of colonisation through building opportunities based on Indigenous governance regimes, cultural practices to care for land and water, and intergenerational perspectives (Nursey-Bray et al., 2019; Petzold et al., 2020) (Cross-Chapter Box INDIG in Chapter 18) (*very high confidence*).

11.4.1 Aboriginal and Torres Strait Islander Peoples of Australia

The highly diverse Aboriginal and Torres Strait Islander Peoples of Australia have survived and adapted to climate changes such as sea-level rise and extreme rainfall variability during the late Pleistocene era, through intimate place-based Indigenous Knowledge in practice and while losing traditional land and sea Country ownership (Liedloff et al., 2013) (Cross-Chapter-Box INDIG in Chapter 18) including during the Late Pleistocene era (Golding and Campbell, 2009; Nunn and Reid, 2016). They belong to the world's oldest living cultures, continually resident in their own ancestral lands, or 'country', for over 65,000 years (Kingsley et al., 2013; Marmion et al., 2014; Nagle et al., 2017; Tobler et al., 2017; Nursey-Bray and Palmer, 2018). The majority of the Australian Indigenous Peoples live in urban areas in southern and eastern Australia, but are the predominant population in remote areas.

Climate-related impacts on Aboriginal and Torres Strait Islander Peoples, Countries (traditional estates) and cultures have been observed across Australia and are pervasive, complex and compounding(Green et al., 2009) (11.5.1) (*high confidence*). For example, loss of bio-cultural diversity, nutritional changes through availability of traditional foods and forced diet change, water security, and loss of land and cultural resources through erosion and sea-level rise (Table 11.10)](TSRA, 2018). Moreover, these impacts are being experienced now particularly in low-lying geographical areas- especially in the Torres Strait Islands (Mosby, 2012; Kelly, 2014; Murphy, 2019; Hall et al., 2021). Estimates of the loss from fire impacts on ecosystem services that contribute to the wellbeing of remotely-located Indigenous Australians were found to be higher than the financial impacts from the same fires on pastoral and conservation lands (Sangha et al., 2020) and could increase with both financial and non-financial impacts (Box 11.1).

Table 11.10: Climate-related impacts on Aboriginal and Torres Strait Islander Peoples, country and cultures.

Impacts	Implications
Loss of bio-cultural diversity (land, water and sky) (*medium confidence*)	Healthy country is critical to Indigenous Australians' livelihoods, caring for country responsibilities, health and wellbeing. Damage to land can magnify the loss of spiritual connection to land from dispossession from traditional Country and leads to disruption of cultural structures. Climate change impacts can exacerbate and/or accelerate existing threats of habitat degradation and biodiversity loss, and create challenges for traditional stewardship of landscapes (Mackey and Claudie, 2015)
Climate-driven loss of native title and other customary lands (*medium confidence*)	Traditional coastal lands lost through erosion and rising sea level, with associated mental health implications from loss of cultural and traditional artefacts and landscapes, including the destruction and exhumation of ancestral graves and burial grounds. This is also occurring and predicted to intensify in the low-lying islands of the Torres Strait (TSRA, 2018; Hall et al., 2021) and was also noted during the extreme bushfires in Eastern Australia in late 2019 and early 2020.
Changing availability of traditional foods and forced diet change (*medium confidence*)	Human health impacts can be exacerbated by climate change through changing availability of traditional foods and medicines, while outages and high costs of electricity can limit storage of fresh food and medication (Kingsley et al., 2013; Spurway and Soldatic, 2016; Hall and Crosby, 2020)
Changing climatic conditions for subsistence food harvesting (*medium confidence*)	Climate change-induced sea-level rise and saltwater intrusion can limit the capacity for traditional Indigenous floodplain pastoralism, and also affect food security, access and affordability to healthy, nutritional food (Ligtermoet, 2016; Spurway and Soldatic, 2016)
Extreme weather events triggering disasters (*high confidence*)	Increasing frequency or intensity of extreme weather events (floods, droughts, cyclones, heatwaves) can cause disaster responses in remote communities, including infrastructure damage of essential water and energy systems and health facilities (TSRA, 2018; Hall and Crosby, 2020)
Heatwave impacts on human health (*high confidence*)	Heatwaves can occur in many regions. Tropical regions can experience prolonged seasons of high temperatures and humidity levels, resulting in extreme heat stress risks. For example, the Torres Strait Island are already categorised under the U.S. National Oceanic and Atmospheric Administration (NOAA) Heat Index as a danger zone for extreme human health risk during Summer (TSRA, 2018)
Health impacts from changing conditions for vector-borne diseases (*high confidence*)	Climate change can change exposure and increase risk for remote Indigenous Peoples to infection from waterborne and insect-borne diseases, especially if medical services are limited or damaged by extreme weather events. For example, in the Torres Strait Islands the changing climate is affecting the range and extension of the Aedes albopictus and Aedes aegypti mosquitoes that can carry and transmit dengue and other viruses (Horwood et al., 2018; TSRA, 2018)
Unadaptable infrastructure for changing environmental conditions (*high confidence*)	Poorly-designed, inferior quality and unmaintained housing can create health challenges for tenants in extreme heat (Race et al., 2016). Essential community-scale water and energy service infrastructure, unpaved roads, sea walls and storm water drains can fail in extreme weather events (McNamara et al., 2017)

Drinking water security (*medium confidence*)	Predicted continued increases in arid conditions in Australia are expected to reduce the recharge rate of finite groundwater supplies (Barron et al., 2011). For remote communities reliant on groundwater for drinking supplies, this water insecurity creates vulnerabilities from over-extraction and lack of access (Jackson et al., 2019; Hall and Crosby, 2020). This groundwater can also have microbial contamination from sewage and chemicals supporting bacterial growth, such as high iron levels supporting the growth of *Burkholderia pseudomallei* that causes melioidosis in humans and animals (Kaestli et al., 2019). In the Torres Strait, increasing reliance on desalination for drinking water raises costs for fuel and its associated transport (Beal et al., 2018)

Due to ongoing impacts of colonisation, Aboriginal and Torres Strait Islander Peoples have, on average, lower income, poorer nutrition, lower school outcomes and employment opportunities, and higher incarceration and removal of children than non-Indigenous Australians, represented in high comorbidities of chronic diseases and mental health impacts (Marmot, 2011; Green and Minchin, 2014; AIHW, 2015). This relative poverty can reduce climate-adaptive capacities while exacerbating climate change vulnerabilities (Nursey-Bray and Palmer, 2018). In remote Country, this can combine with lack of security for food and water, non-resilient housing and extreme weather events, contributing to migration off traditional Country and into towns and cities- with flow-on social impacts such as homelessness, dislocation from community and family, and disconnection from country and spirituality (Mosby, 2012; Brand et al., 2016).

Recognition of the role Aboriginal and Torres Strait Islander Peoples in identifying solutions to the impacts of climate change is slowly emerging (UN, 2018) having been largely excluded from meaningful representation from the conception of climate change dialogue, through to debate and decision-making (Nursey-Bray et al., 2019). Honouring the United Nations' Declaration on the Rights of Indigenous Peoples and social justice values would support self-determination and the associated opportunity for Indigenous Australians to develop adaptation responses to climate change (Langton et al., 2012; Nursey-Bray and Palmer, 2018; Nursey-Bray et al., 2019), including the adaptive capacity opportunities available through Indigenous Knowledge (Liedloff et al., 2013; Petheram et al., 2015; Stewart et al., 2019) (Cross-Chapter Box INDIG in Chapter 18). The Uluru Statement from the Heart proposes a pathway and roadmap forward for enhanced representation of Aboriginal and Torres Strait Islander Peoples in decision-making in Australia (Ululru Statement, 2017). Table 11.11 provides examples of traditional Indigenous practices of adaptation to a changing climate. However, due to Indigenous methods of knowledge sharing and knowledge holding, such knowledge relies disproportionately on elders and seniors, who form a very small portion of the total Aboriginal and Torres Strait Islander Peoples of Australia, and is limited in the formal literature (ABS, 2016).

Table 11.11: Examples of Aboriginal and Torres Strait Islander Peoples' practices of adaptation to a changing climate

'Caring for Country': Traditional Practices for Holistic Land and Cultural Protection and Adaptation in a Changing Climate	Source
Indigenous Protected Area (IPA) management plans enable culturally and ecologically compatible development that contribute to local Indigenous economies	(Mackey and Claudie, 2015).
IPAs can avoid the potential for 'nature–cultures dualism' that locks out Indigenous access in some protected area legislation, as they are based on relational values informed by local Indigenous Knowledge	(Lee, 2016)
Fire management using cultural practices can achieve greenhouse gas emission targets while also maintaining Indigenous cultural heritage.	(Robinson et al., 2016)
Indigenous Ranger programmes provide a means for Indigenous-guided land management, including for fire management and carbon abatement, fauna studies, medicinal plant products, weed management and recovery of threatened species	(Mackey and Claudie, 2015)

Faunal field surveys can engage local, bounded and fine-scale intuitive species location by Indigenous knowledge holders and their knowledge used for conservation planning	(Wohling, 2009; Ziembicki et al., 2013)
Cultural flows in waterways are a demonstration of cultural knowledge, values and practice in action as they are informed by Indigenous knowledge, bound by water-dependent values, and define when and where water is to be delivered - particularly in a changing climate.	(Bark et al., 2015; Taylor et al., 2017)

11.4.2 Tangata Whenua – New Zealand Māori

Māori society faces diverse impacts, risks and opportunities from climate change (Table 11.12). Studies exploring climate change impacts, scenarios, policy implications, adaptation options and tools for Māori society have increased substantially e.g. (King et al., 2012; Bargh et al., 2014; Jones et al., 2014; Bryant et al., 2017; Awatere et al., 2018; Colliar and Blackett, 2018). Māori priorities surrounding climate change risks and natural resource management have been articulated in planning documents by many Māori kin-groups e.g. (Ngāti Tahu- Ngāti Whaoa Rūnanga Trust, 2013; Raukawa Settlement Trust, 2015; Ngai-Tahu, 2018; Te Urunga Kea - Te Arawa Climate Change Working Group, 2021) reflecting the importance of reducing vulnerability and enhancing resilience to climate impacts and risks through adaptation and mitigation.

Māori have long-term interests in land and water and are heavily invested in climate sensitive sectors (agriculture, forestry, fishing, tourism and renewable energy) (King et al., 2010). Large proportions of collectively owned land already suffer from high rates of erosion (Warmenhoven et al., 2014; Awatere et al., 2018) which are projected to be exacerbated by climate change induced extreme rainfalls (RSNZ, 2016; Awatere et al., 2018) (*high confidence*). Changing drought occurrence, particularly across eastern and northern New Zealand, is also projected to affect primary sector operations and production (King et al., 2010; Smith et al., 2017; Awatere et al., 2018) (*medium confidence*). Further, many Māori-owned lands and cultural assets such as marae and urupa are located on coastal lowlands vulnerable to sea-level rise impacts (Manning et al., 2014; Hardy et al., 2019) (*high confidence*). Māori tribal investment in fisheries and aquaculture faces substantial risks from changes in ocean temperature and acidification, and the downstream impacts for species distribution, productivity and yields (Law et al., 2016) (*medium confidence*). A clearer understanding of climate change risks and the implications for sustainable outcomes can enable more informed decisions by tribal organisations and governance groups.

Changing climate conditions are projected to exacerbate health inequities faced by Māori (Bennett et al., 2014; Jones et al., 2014; Hopkins, 2015) (*medium confidence*). The production and ecology of some keystone cultural flora and fauna may be impacted by projected warming temperatures and reductions in rainfall (RSNZ, 2016; Bond et al., 2019; Egan et al., 2020) (*medium confidence*). Obstruction of access to keystone species is expected to adversely impact customary practice, cultural identity and well-being (Jones et al., 2014; Bond et al., 2019)(*medium confidence*). Social-cultural networks and conventions that promote collective action and mutual support are central features of many Māori communities, and these practices are invaluable for initiating responses to, and facilitating recovery from, climate stresses and extreme events (King et al., 2011; Hopkins et al., 2015). Māori tribal organisations have a critical role in defining climate risks and policy responses (Bargh et al., 2014; Parsons et al., 2019) as well as entering into strategic partnerships with business, science, research and government to address these risks (Manning et al., 2014; Beall and Brocklesby, 2017; CCATWG, 2017) (*high confidence*).

More integrated assessments of climate change impacts, adaptation and socio-economic risk for different Māori groups and communities, in the context of multiple stresses, inequities and different ways of knowing and being (King et al., 2013; Schneider et al., 2017; Henwood, 2019) would assist those striving to evaluate impacts and risks, and how to integrate these assessments into adaptation plans (*high confidence*). Better understanding of the social, cultural and fiscal implications of sea-level rise is urgent (PCE, 2015; Rouse et al., 2017; Colliar and Blackett, 2018), including what duties local and central Government might have with respect to actively upholding Māori interests under the Treaty of Waitangi (Iorns Magallanes, 2019) (*high confidence*). Intergenerational approaches to climate change planning will become increasingly important, elevating political discussions about conceptions of rationality, diversity and the rights of non-human entities (Ritchie, 2013; Carter et al., 2018; Ruru, 2018; Munshi et al., 2020) (*high confidence*).

Table 11.12: Climate-related impacts and risks for Tangata Whenua New Zealand Māori

Impact	Risks
Changes in drought occurrence and extreme weather events	Risks to Māori tribal investment in forestry, agriculture and horticulture sector operations and production, particularly across eastern and northern New Zealand (King et al., 2010; Awatere et al., 2018; Hardy et al., 2019)(*medium confidence*)
Changes in rainfall, temperature, drought, extreme weather events and ongoing sea-level rise	Risks to potable water supplies (availability and quality) for remote Māori populations (RSNZ, 2016; Henwood, 2019)(*medium confidence*)
Changes in rainfall, temperature, drought, extreme weather events and ongoing sea-level rise	Risks of exacerbating existing inequities (e.g. health, economic, education and social services), social cohesion and well-being (Bennett et al., 2014; Jones et al., 2014)(*medium confidence*)
Changes in rainfall regimes and more intense drought combined with degradation of lands and water	Risks to the distribution and survival of cultural keystone flora and fauna, as well as cascading risks for Māori customary practice, cultural identity and well-being (King et al., 2010; RSNZ, 2016; Bond et al., 2019)(*high confidence*)
Changes in ocean temperature and acidification	Risks to nearshore and ocean species productivity and distribution, as well as cascading risks for Māori tribal investment in the fisheries and aquaculture sectors (King et al., 2010; Law et al., 2016)(*medium confidence*)
Sea-level rise induced erosion, flooding and saltwater intrusion	Risks to Māori-owned coastal lands and economic investment as well as risks to community wellbeing from displacement of individuals, families and communities (Manning et al., 2014; Smith et al., 2017; Hardy et al., 2019)(*high confidence*)
Sea-level rise induced erosion, inundation and saltwater intrusion	Risks to Māori cultural heritage as well as cascading risks for tribal identity and spiritual well-being (King et al., 2010; Manning et al., 2014; RSNZ, 2016)(*medium confidence*)
Impacts of climate change, adaptation and mitigation actions	Risks that governments are unable to uphold Māori interests, values and practices under the Treaty of Waitangi, creating new, modern-day breaches of the Treaty of Waitangi (Iorns Magallanes, 2019; MfE, 2020a)(*high confidence*)

11.5 Cross-Sectoral and Cross-Regional Implications

The impacts and adaptation processes described in sections 11.3 and 11.4 are focused on specific sectors, systems and Indigenous Peoples. Added complexity, risk and adaptation potential stem from cross-sectoral and cross-regional inter-dependencies.

11.5.1 Cascading, compounding and aggregate impacts

11.5.1.1 Observed Impacts

Climate impacts are cascading, compounding and aggregating across sectors and systems due to complex interactions (*high confidence*) (Pescaroli and Alexander, 2016; Challinor et al., 2018; Zscheischler et al., 2018; Steffen et al., 2019; AghaKouchak et al., 2020; CoA, 2020e; Lawrence et al., 2020b; Simpson et al., 2021) (Box 11.1; Box 11.3; Box 11.4; Box 11.5; Box 11.6). Cascading impacts propagate via interconnections and systemic factors, including supply chains, shared reliance on connected biophysical systems (e.g. water catchments and ecosystems), infrastructure and essential goods and services, and the exercise of governance, leadership, regulation, resources and standard practices (e.g. in planning and building codes), including lock-in of past decisions and experience (CSIRO, 2018; Lawrence et al., 2020b). The capacity of critical systems such as Information, Communication and Technology, water infrastructure, health care, electricity and transport networks are being stretched, with impacts cascading to other systems and places, exacerbating existing hazards and generating new risks (Cradock-Henry, 2017) (11.3.6;11.3.10; Box 11.1). Temporal or spatial overlap of hazards (e.g. drought, extreme heat and fire; drought followed by extreme rainfall) are compounding impacts (Zscheischler et al., 2018) and affecting multiple sectors.

In Australia, extreme events such as heatwaves, droughts, floods, storms and fires have caused deaths and injuries (Deloitte, 2017a) (11.3.5.1), and affected many households, communities and businesses via impacts on ecosystems, critical infrastructure, essential services, food production, the national economy, valued places and employment. This has created long-lasting impacts (e.g. mental health, homelessness, health incidents and reduced health services) (Brown et al., 2017; Brookfield and Fitzgerald, 2018; Rychetnik et al., 2019) and reduced adaptive capacity (Friel et al., 2014; O'Brien et al., 2014; Ding et al., 2015; CoA, 2020e) (Box 11.1, Box 11.3, 11.3.1-11.3.10).

In New Zealand, extreme snow, rainfall and wind events have combined to impact road networks, power and water supply, and have impeded interdependent wastewater and stormwater services and business activities (Deloitte, 2019; Lawrence et al., 2020b; MfE, 2020a) (Box 11.4). Community and infrastructure services are periodically disrupted during extreme weather events, triggering impacts from the interdependencies across enterprises and individuals (Glavovic, 2014; Paulik et al., 2021).

Slow onset climate change impacts have also had cascading and compounding effects. For example, degradation of the Great Barrier Reef by ocean heating, acidification and non-climatic pressures (Marshall et al., 2019), repeated pluvial, fluvial and coastal flooding of some settlements (Paulik et al., 2019a; Paulik et al., 2020), long droughts and water insecurity in rural communities (Tschakert et al., 2017), and the gradual loss of species and ecological communities, have caused substantial ecological, social and economic losses. Indigenous peoples have especially been impacted by multiple and complex losses (Johnson et al., 2021) (11.4).

11.5.1.2 Projected Impacts

Cascading, compounding and aggregate impacts are projected to grow due to a concurrent increase in heatwaves, droughts, fires, storms, floods and sea level (*high confidence*) (CSIRO, 2020; Lawrence et al., 2020b). Urban wastewater, stormwater and water supply systems are particularly vulnerable in New Zealand (Paulik et al., 2019a; Hughes et al., 2021) to pluvial flooding (Box 11.4) and to sea-level rise (Box 11.6), with flow-on effects to settlements, insurance and finance sectors, and governments (Lawrence et al., 2020b). Furthermore, consecutive heavy rainfall events in late summer and autumn, following drought conditions in low-lying modified wetland areas, have implications for the operation of flood control infrastructure as increased rainfall intensity, land subsidence, and sea-level rise compound and result in the retention of floodwaters (Pingram et al., 2021).

In Australia, the aggregate loss of wealth due to climate-induced reductions in productivity across agriculture, manufacturing and service sectors is projected to exceed A$19 billion by 2030, A$211 billion by 2050 and A$4 trillion by 2100 for RCP8.5 (Steffen et al., 2019) (Table 11.13). Projected impacts also cascade across national boundaries via value chains, markets, movement of humans and other organisms, and geopolitics (e.g. migration from near-neighbours as a pathway for adaptation, mobile climate-sensitive diseases and changes in production and trade patterns) (Lee et al., 2018; Nalau and Handmer, 2018; Schwerdtle et al., 2018; Dellink et al., 2019). The scale of impacts is projected to challenge the adaptive capacity of sectors, governments and institutions (Steffen et al., 2019), including the insurability of assets and risks to lenders (Storey and Noy, 2017).

11.5.1.3 Adaptation

Coordinating adaptation strategies and addressing underlying exposure and vulnerability can increase resilience to cascading, compounding and aggregate impacts (Table 11.17; 11.7.3) (*high confidence*). Systems understanding, network analysis, stress testing, spatial mapping, collaboration, information sharing and interoperability across states, sectors, agencies and value chains, as well as national scale facilitation, can increase adaptive capacity (Espada et al., 2015; CoA, 2020e; Cradock-Henry et al., 2020b; Jozaei et al., 2020). Greater system diversity, modularity, redundancy, adaptability and decentralised control can reduce the risk of cascading failures and system breakdown (Sinclair et al., 2017; Sellberg et al., 2018). Addressing existing vulnerabilities in systems can reduce susceptibility and improve the resilience of interdependent systems (11.7.3). Multi-level leadership, including national and sub-national policies, laws and finance can reduce and manage aggregate risks supported by the enablers in Table 11.17.

Anticipatory governance and agile decision making can build resilience to cascading, compounding and aggregate impacts (Boston, 2016; Deloitte, 2016; Steffen et al., 2019; CoA, 2020e; CSIRO, 2020; Lawrence et al., 2020b; MfE, 2020c) (*high confidence*). There is uncertainty about whether standard integrated assessment models can estimate cascading and compounding impacts across systems and sectors, but systems methodologies and social network analysis hold promise (Stoerk et al., 2018; Cradock-Henry et al., 2020b). Interventions at the landscape, building and individual scale can reduce the negative health effects of current and future extreme heat, if integrated in well-communicated heat action plans with robust surveillance and monitoring (Jay et al., 2021).

In Australia, the National Disaster Risk Reduction Framework (CoA, 2018b), National Recovery and Resilience Agency, and Australian Climate Service (CoA, 2021) can provide some support for adaptation across multiple sectors. New Zealand has effective partnerships across critical infrastructure through lifelines groups, but organisational silos and lack of stress testing of plans hamper coordinated decision making during crises and for adaptation (Brown et al., 2017; Lawrence et al., 2020b). The New Zealand national risk assessment, national adaptation plan, forthcoming Climate Change Adaptation Act, and monitoring of adaptation progress by the Climate Change Commission, provide a framework for anticipating climate change risks (MfE, 2020a).

11.5.2 Implications for National Economies

The implications of climate change for national economies are significant (*high confidence*). The costs associated with lost productivity, disaster relief expenditure and unfunded contingent liabilities represent a major risk to financial system stability (MfE, 2020a). Costs include significant and often long-term social impacts, temporary dislocation, business disruption, and impacts on employment, education, community networks, health and wellbeing (Deloitte, 2017a). Climate change disrupts international patterns of agricultural production and trade in ways that may be negative, but may also lead to new opportunities for agriculture (Mosnier et al., 2014; Nelson et al., 2014; Lee et al., 2018). Net exports may increase following global climate shocks (Lee et al., 2018), but the longer term effects on GDP are *likely* to be negative (Dellink et al., 2019).

11.5.2.1 Observed Impacts

In Australia, during 2007-2016, total economic costs from natural disasters averaged A$18.2 billion per year (Deloitte, 2017a). Individual weather-related disaster costs across multiple sectors have exceeded A$4 billion, such as the 2009 fires in Victoria (Parliament of Victoria, 2010), the 2010-2011 floods in south-east Queensland (Deloitte, 2017b), the 2019 floods in northern Queensland (Deloitte, 2019) and the 2019-2020 fires in southern and eastern Australia (Box 11.1).

In New Zealand, the annual cost of rural fire to the economy has been estimated at NZ$67 million, with indirect 'costs' potentially 2–3 times direct costs (Scion, 2018). Insured losses from weather-related disasters cost almost NZ$1 billion during 2015-2021 (ICNZ, 2021). Floods cost the New Zealand economy at least NZ$120 million for privately insured damages between 2007 and 2017 (D. Frame et al., 2018). The 2007/08 drought cost NZ$3.2 billion and the 2012/13 drought cost NZ$1.6 billion, of which about 20% could be attributed to anthropogenic climate change (Frame et al., 2020) (11.5.3.1).

The intangible costs of climate impacts - including death and injury, impacts on health and wellbeing, education and employment, community connectedness, and the loss of ancestral lands, cultural sites and ecosystems (Barnett et al., 2016; Warner et al., 2019) - affect multiple sectors and systems and exacerbate existing vulnerabilities. While often incommensurable, intangible costs may be far higher than the tangible costs. For example, following the Victorian fires in 2009, the tangible costs were A$3.1 billion while the intangible costs were A$3.4 billion; following the Queensland floods in 2010/11, the tangible costs were A$6.7 billion while the intangible costs were A$7.4 billion (Deloitte, 2016).

11.5.2.2 Projected Impacts

The economic impact increases with higher levels of warming (*high confidence*) but there is a wide range in projections. Conservative estimates for the impacts of a 1, 2 or 3°C global warming (relative to 1986-2005) on Australian GDP growth are -0.3%/year, -0.6%/year and -1.1%/year, respectively, while for New Zealand the estimates are -0.1%, -0.4%/year and -0.8%/year, respectively (Kompas et al., 2018). More detailed modelling indicates a loss in Australia's GDP of 6% by 2070 for 3°C global warming, while a 2.6% GDP rise by 2070 is possible for 1.5°C global warming (Deloitte, 2020). The potential for much more severe effects on GDP is shown in recent estimates which attempt to account for the increased severity of uncertain effects (e.g. up to 18.5% reduction in Australia's GDP by mid-Century) (Swiss Re, 2021).

In Australia, the total annual cost of damage due to floods, coastal inundation, forest fires, subsidence and wind (excluding cyclones) is estimated to increase 55% between 2020 and 2100 for RCP8.5 (Mallon et al., 2019). National damage costs and impacts on asset values could be significant (Table 11.13). The macro-economic shocks induced from climate change, including reduced agricultural yields, damage to property and infrastructure and commodity price increases, could lead to significant market corrections and potential financial instability (Steffen et al., 2019). Under a 'slow decline' scenario by 2060 where Australia fails to adequately address climate change and sustainability challenges, GDP is projected to grow at 0.7% less per year and real wages would be 50% lower than under an 'outlook scenario' where Australia meets climate change and sustainability challenges (CSIRO, 2019).

In New Zealand, the value of buildings exposed to coastal inundation could increase by NZ$2.55 billion for every 0.1 m increment in sea level, i.e. $25.5 billion for a 1.0 m sea-level rise (Paulik et al., 2020). Greater understanding is required of the distributional impacts, the rate of change of costs over time and the economic implications of delayed action (Warner et al., 2020).

Table 11.13: Economy-wide projected costs (A$) of climate change in Australia. (Estimates are not comparable across studies because different methods have been used. Estimates for later in the century are speculative as both impacts and adaptation are uncertain).

Impact	2030	2050	2090	Reference
Damage-related loss of property value in Australia	$571 billion	$611 billion	$770 billion	(Steffen et al., 2019)
Property damage in Australia		$91 billion per year	$117 billion per year	(Steffen et al., 2019)
Loss of asset value of road infrastructure (including freeways, main roads and unsealed roads) in Australia at risk of a sea-level rise of 1.1 metres by 2100			$46-60 billion	(DCCEE, 2011)
Loss of asset value of rail and tramway infrastructure in Australia at risk of a sea-level rise of 1.1 metres by 2100			$4.9-6.4 billion	(DCCEE, 2011)
Loss of asset value of residential buildings in Australia at risk of a sea-level rise of 1.1 metres by 2100 (2008 replacement value)			$51-72 billion	(DCCEE, 2011)
Loss of asset value of light industrial buildings (used for warehousing, manufacturing, and assembly activities and services) in Australia at risk of a sea-level rise of 1.1 metres by 2100			$4.2-6.7 billion	(DCCEE, 2011)

Loss of asset value of commercial buildings (used for wholesale, retail, office and transport activities) in Australia at risk of a sea-level rise of 1.1 metres by 2100 (2008 replacement value)			$58-81 billion	(DCCEE, 2011)
Accumulated loss of wealth due to reduced agricultural productivity and labour productivity	$19 billion	$211 billion	$4.2 trillion	(Steffen et al., 2019)
Wind damage to dwellings in Cairns, Townsville, Rockhampton and south-east Queensland (assuming a 4 per cent discount rate)	$3.8 billion	$9.7 billion	$20 billion	(Stewart and Wang, 2011)
Damage to Australian coastal residential buildings due to sea-level rise (A1B scenario, 3.5°C global warming)			$8 billion	(Wang et al., 2016)

11.5.2.3 Adaptation

Investments in mitigation and adaptation can help reduce or prevent economic losses now and in the coming decades (IPCC, 2018; Steffen et al., 2019), however the costs and the benefits of mitigation and adaptation are not well understood in the region (CSIRO, 2019; MfE, 2020a) (*high confidence*).

In New Zealand, the emphasis has been on rebuilding after climate disasters, rather than anticipatory adaptation (Boston and Lawrence, 2018). Australia is similarly focused on disaster response and recovery, even though investment in disaster resilience can provide a cost:benefit ratio of 1:2 to 1:11 through reduced post-disaster recovery and reconstruction (GCA, 2019). Recent Australian and state government spending on direct recovery from disasters was around A$2.75 billion per year, compared to funding for natural disaster resilience of approximately A$0.1 billion per year (Deloitte, 2017b). The Australian Government is supporting most of the 80 recommendations from the Royal Commission into National Natural Disaster Arrangements, including establishing a disaster advisory body and a resilience and recovery agency (CoA, 2020e; CoA, 2020b). Australia and New Zealand provide humanitarian and disaster assistance across the Pacific, which is increasingly focused on climate adaptation and the Sustainable Development Goals (Brolan et al., 2019) as cyclones and floods become amplified by climate change (Fletcher et al., 2013) (Table 11.3). Climate change may increase current migration flows to and impacts on diaspora in Australia and New Zealand from near neighbour island nations, as they become increasingly stressed by rising seas, higher temperatures, more droughts and stronger storms (Nalau and Handmer, 2018).

Delaying adaptation to climate risks may result in higher overall costs in future when adaptation is more urgent and impacts more extreme (Boston and Lawrence, 2018; IPCC, 2018) (*medium confidence*). Estimates of the magnitude of adaptation costs and benefits in the region are localised and sectoral, e.g. (Thamo et al., 2017) or regionally aggregated (Joshi et al., 2016). Adaptation costs are expected to increase markedly for higher RCPs, e.g. a tripling of expected costs between RCP2.6 and RCP8.5 for sea-level rise protection in Australia (Ware et al., 2020). Existing governance arrangements for funding adaptation are inadequate for the scope and scale of climate change impacts anticipated; dedicated funding mechanisms that can be sustained over generations can enable more timely adaptation (Boston and Lawrence, 2018).

11.6 Key Risks and Benefits

Nine key risks have been identified (Table 11.14) based on four criteria: magnitude, likelihood, timing and adaptive capacity (Chapter 16). Most of the key risks are similar to those in the IPCC AR5 Australasia chapter (Reisinger et al., 2014), but the emphasis here is on specific systems affected by multiple hazards rather than specific hazards affecting multiple systems. The selection of key risks reflects what has been observed, projected and documented, noting that there are gaps in knowledge, and a lack of knowledge does not imply a lack of risk (11.7.3.3). Key risks are grouped into four categories:

Ecosystems at critical thresholds where recent climate change has caused significant damage and further climate change may cause irreversible damage, with limited scope for adaptation

1. Loss and degradation of coral reefs in Australia and associated biodiversity and ecosystem service values due to ocean warming and marine heatwaves (11.3.2.1, 11.3.2.2, Box 11.2).
2. Loss of alpine biodiversity in Australia due to less snow (11.3.1.1, 11.3.1.2).

Key risks that have potential to be severe but can be reduced substantially by rapid, large-scale and effective mitigation and adaptation

3. Transition or collapse of alpine ash, snowgum woodland, pencil pine and northern jarrah forests in southern Australia due to hotter and drier conditions with more fires (11.3.1.1, 11.3.1.2)
4. Loss of kelp forests in southern Australia and southeast New Zealand due to ocean warming, marine heatwaves and overgrazing by climate-driven range extensions of herbivore fish and urchins (11.3.2.1, 11.3.2.2).
5. Loss of natural and human systems in low-lying coastal areas due to sea level rise (11.3.5, Box 11.6).
6. Disruption and decline in agricultural production and increased stress in rural communities in south-western, southern and eastern mainland Australia due to hotter and drier conditions (11.3.4, 11.3.5, Box 11.3).
7. Increase in heat-related mortality and morbidity for people and wildlife in Australia due to heatwaves (11.3.5.1, 11.3.5.2, 11.3.6.1, 11.3.6.2).

Key cross-sectoral and system-wide risk

8. Cascading, compounding and aggregate impacts on cities, settlements, infrastructure, supply-chains and services due to wildfires, floods, droughts, heatwaves, storms and sea-level rise (11.5.1.1, 11.5.1.2, Box 11.1, Box 11.4, Box 11.6).

Key implementation risk

9. Inability of institutions and governance systems to manage climate risks. (11.5; 11.7.1, 11.7.2, 11.7.3).

At higher levels of global warming, adaptation costs increase, options become limited and risks grow. The 'burning embers' diagram in Figure 11.6 has four IPCC risk categories: "undetectable", "moderate", "high" and "very high", with transition points defined by different global warming ranges. The embers are indicative, based on an assessment of available literature and expert judgement (Supplementary Material SM 11.2). Outcomes for low and moderate adaptation have been compared, with the latter including both incremental and transformative options. Illustrative examples of adaptation pathways are shown in Figure 11.7 for low-lying coastal areas and Figure 11.8 for heat-related mortality. These figures highlight thresholds at which adaptation options become ineffective, and possible combinations of strategies and options implemented at different times to manage emerging risks and changing risk profiles.

Caveats: (a) key risks are assessed at regional scales, so they do not include other risks for finer scales or specific groups; (b) non-climatic vulnerabilities are held constant for simplicity; (c) the assessment of risk ratings at different levels of global warming is limited by available literature; (d) risks increase with global warming, despite the lack of an IPCC risk rating beyond "very high"; and (e) the feasibility and effectiveness of adaptations options were not assessed due to limited literature (11.7.3.3).

The New Zealand National Climate Change Risk Assessment (MfE, 2020a) identified the priority risks from climate change for New Zealand based on a literature review and expert elicitation. The top two risks in each of five domains are: *Natural environment* (1) risks to coastal ecosystems due to ongoing sea-level rise and extreme weather events, (2) risks to indigenous ecosystems and species from invasive species; *Human environment* (1) risks to social cohesion and community well-being from displacement of people, (2) risks of exacerbating existing inequities and creating new and additional inequities from distribution impacts; *Economy* (1) risks to governments from economic costs associated with lost productivity, disaster relief expenditure and unfunded contingent liabilities, (2) risks to the financial system from instability; *Built environment* (1) risk to potable water supplies due to changes in rainfall, temperature, drought, extreme weather events and ongoing sea-level rise,(2) risks to buildings due to extreme weather events, drought, increased fire weather and ongoing sea-level rise; *Governance* (1) risk of maladaptation due to practices, processes and tools that do not account for uncertainty and change over long timeframes, and (2) risk that climate change impacts across all domains will be exacerbated, because current institutional arrangements are not fit for adaptation. Not all of these risks feature as key risks for the wider Australasia region; nonetheless they are reflected across Chapter 11 and remain priorities for New Zealand to address through the National Adaptation Plan, its implementation and monitoring.

Short-term benefits from climate change may include reduced winter mortality, reduced energy demand for winter heating, increased agriculture productivity and forest growth in south and west New Zealand, and increased forest and pasture growth in southern Australia except where rainfall and soil nutrients are limiting (11.3.4; 11.3.6; 11.3.10) (*medium confidence*).

Table 11.14: Key risks from climate change based on assessment of the literature and expert judgement (Supplementary Material SM 11.2**)**. Assessment criteria are magnitude, timing, likelihood and adaptive capacity. Risk drivers are hazards, exposure and vulnerability. Adaptation options describe ways in which risks can be reduced. Confidence ratings are based on the amount of evidence and agreement between lines of evidence**.**

Key risk (*confidence rating*) (Chapter reference)	Consequences influenced by hazards, exposure, vulnerability and adaptation options
1. Loss and degradation of tropical shallow coral reefs and associated biodiversity and ecosystem service values in Australia due to ocean warming and marine heatwaves (*very high confidence*) (11.3.2, Box 11.2)	Consequences: Widespread destruction of coral reef ecosystems and dependent socio-ecological systems. Three mass bleaching events from 2016-2020 have already caused significant loss of corals in shallow-water habitats across the Great Barrier Reef. Globally, bleaching is projected to occur twice each decade from 2035 and annually after 2044 under RCP 8.5 and annually after 2051 under RCP4.5. A 3ºC global warming could cause over six times the 2016 level of thermal stress. Hazards: Increase in background warming and marine heatwave events degrade reef-building corals by triggering coral bleaching events at a frequency greater than the recovery time. Fish populations also decline during and following heat wave events. Exposure: Increasing geographic area affected by rate and severity of ocean warming Vulnerability: Vulnerability to increases in sea temperature is already very high because of other stressors on the ecosystem, including sediment, pollutants, and overfishing. Adaptation options: Minimising other stressors. Efforts on the Great Barrier Reef may slow the impacts of climate change in small sections or reduce short-term socio-economic ramifications, but will not prevent widespread bleaching.
2. Loss of alpine biodiversity in Australia due to less snow (*high confidence*) (11.3.1, Tables 11.2, 11.3, 11.4, 11.5)	Consequences: Loss of endemic and obligate alpine wildlife species and plant communities (feldmark and short alpine herb-fields) as well as increased stress on snow-dependent plant and animal species. Hazards: Projected decline in annual maximum snow depth by 2050 is 30-70% (low emissions) and 45-90% (high emissions); projected increases in temperature and decreases in precipitation. Exposure: Alpine species face elevation squeeze due to lack of nival zone and alpine environments have restricted geographic extent. Vulnerability: Narrow ecological niche of species including snow-related habitat requirements; encroachment from sub-Alpine woody shrubs; vulnerability generated by non-climatic stressors including weeds and feral animals, especially horses Adaptation options: Reducing pressure on alpine biodiversity from land uses that degrade vegetation and ecological condition, along with weed and pest management.

3. Transition or collapse of alpine ash, snowgum woodland, pencil pine and northern jarrah forests in southern Australia due to hotter and drier conditions with more fires (*high confidence*) (11.2, 11.3.1, 11.3.2, Box 11.1)	Consequences: If regenerative capacities of the dominant (framework) canopy tree species are exceeded, a long lasting or irreversible transition to a new ecosystem state is projected with loss of characteristic and framework species including loss of some narrow range endemics. Hazards: Hotter and drier conditions have increased extreme fire weather risk since 1950, especially in southern and eastern Australia. The number of severe fire weather days is projected to increase 5-35% (RCP2.6) and 10-70% (RCP8.5) by 2050 Exposure: Shift in landscape fire regimes to larger, more intense and frequent wildfires over extensive areas (~10 million hectares) of forests and woodlands from longer fire seasons and more hazardous fire conditions and increasing human-sourced ignitions from urbanisation and projected increase in frequency of lightning strikes Vulnerability: The resilience and adaptive capacity of the forests is being reduced by ongoing land clearing and degrading land management practices Adaptation options: Increased capacity to extinguish wildfires during extreme fire weather conditions; avoiding and reducing forest degradation from inappropriate forest management practices and land use.
4. Loss of kelp forests in southern Australia and southeast New Zealand due to ocean warming, marine heatwaves and overgrazing by climate-driven range extensions of herbivore fish and urchins (*high confidence*) (11.3.2)	Consequences: Observed decline in giant kelp in Tasmania since 1990, with less than 10% remaining by 2011 due to ocean warming. Extensive loss of kelp -140,187 hectares across Australia. Loss of bull kelp in southern New Zealand, replaced by the introduced kelp following the 2017/18 marine heatwave. Further loss of native kelp is projected with warming oceans. Hazards: Ocean warming and marine heatwave events Exposure: Coastal waters around Australia and New Zealand Vulnerability: Giant kelp are already Federally listed in Australia as an endangered marine community type. In Australia, kelp forests are vulnerable to nutrient poor East Australian Current waters pushing further south, warming waters and increased herbivory from range-extending species. Adaptation options: Minimizing other stressors, local restoration, and transplantation of heat-tolerant phenotypes.
5. Loss of human and natural systems in low-lying coastal areas from ongoing sea-level rise (*high confidence*) (11.2, 11.3.2, 11.3.5, 11.3.10, 11.4, Table 11.3; Box 11.6)	Consequences: Nuisance and extreme coastal flooding are already occurring due to sea-level rise (SLR). For 0.2-0.3 m SLR, coastal flooding is projected to become more frequent, e.g. current 1-in-100 year flood would occur every year in Wellington and Christchurch. For 0.5 m SLR, the value of buildings in New Zealand exposed to coastal inundation could increase by NZ$12.75 billion and the current 1-in-100 year flood in Australia could occur several times a year. For 1.0 m SLR, the value of exposed assets in New Zealand would be NZ$25.5 billion. For 1.1 m SLR, the value of exposed assets in Australia would be A$164-226 billion. This would be associated with displacement of people, disruption and reduced social cohesion, degraded ecosystems, loss of cultural heritage and livelihoods, and loss of traditional lands and sacred sites. Hazards: Rising sea level (0.2-0.3 m by 2050, 0.4-0.7 m by 2090), storm surges, rising ground water tables. Exposure: Population growth, new and infill urbanization, tourism developments in low-lying coastal areas. Buildings, roads, railways, electricity and water infrastructure. Torres Strait Island and remote Māori communities are particularly exposed and sensitive. Vulnerability: Ineffective planning regulations, reduced availability and increased cost of insurance, and costs to governments as insurers of last resort. Inadequate investment in avoidance and preparedness exacerbating underlying social vulnerabilities. Financial and physical capacities to cope and adapt are uneven across populations, creating equity issues. Adaptation options: Risk reduction coordinated across all levels of government with communities. Statutory planning frameworks, decision tools and funding mechanisms that can address the changing risk. Planning and land use decisions, including managed retreat where it is inevitable. Improved capacity of emergency services, early warning systems,

	improved planning and regulatory practice and building and infrastructure design standards. Options that anticipate risk and adjust as conditions change.
6. Disruption and decline in agricultural production and increased stress in rural communities across south western, southern and eastern mainland Australia due to hotter and drier conditions. (*high confidence*) (11.2, 11.3.4, 11.3.6.3, 11.4.1, Table 11.11, Boxes 11.1, 11.3)	Consequences: Projected decline in crop, horticulture and dairy production. e.g. decline in median wheat yields by 2050 of up to 30% in south-west Australia and up to 15% in South Australia. Increased heat stress in livestock by 31–42 days per year by 2050. Reduced winter chilling for horticulture. Increased smoke impacts for viticulture. Flow-on effects for agricultural supply chains, farming families and rural communities across south-western, southern and south-eastern Australia, including the Murray-Darling Basin (MDB). Hazards: Hotter and drier conditions with constraints on water resources and more frequent and severe droughts in south-western, southern and eastern Australia. Exposure: Across south western, southern and eastern Australia, many production regions are exposed including the MDB which supports agriculture worth A$24 billion/year, 2.6 million people in diverse rural communities, and important environmental assets containing 16 Ramsar listed wetlands. Vulnerability: Existing financial, social, health and environmental pressures on rural, regional and remote communities. Existing competition for water resources among communities, industries and environment, and uncertainty about sharing of water under a drying climate. Adaptation options: Improved governance and collaboration to build rural resilience, including regional and basin-scale initiatives. Improved water policies and initiatives (e.g. MDB Plan) and changes in management and technologies. Resilience-focused planning for rural settlements, land-use, industry, infrastructure and value chains. Adoption of information, tools and methods to better manage uncertainty, variability and change. Incremental changes in farm management practices (e.g. stubble retention, weed control, water-use efficiency, sowing dates, cultivars). In some regions, major changes may be necessary, e.g. diversification in agricultural enterprises, transition to different land-uses (e.g. carbon sequestration, renewable energy production, biodiversity conservation) or migration to another area. Flows in waterways based on Indigenous knowledge to protect cultural assets.
7. Increase in heat-related mortality and morbidity for people and wildlife in Australia (*high confidence*) (11.2, 11.3.1, 11.3.5, 11.3.6, 11.4)	Consequences: During 1987-2016, natural disasters caused 971 deaths and 4,370 injuries, with more than 50% due to heatwaves. Annual increases are projected for excess deaths, additional hospitalisations and ambulance callouts. Heatwave related excess deaths in Melbourne, Sydney and Brisbane are projected to increase by about 300/year (RCP2.6) to 600/year (RCP8.5) during 2031-2080 relative to 142/year during 1971-2020, assuming no adaptation. Significant heat-related mortality of wildlife species (flying foxes, freshwater fish) has been observed and is projected to increase. Hazards: Increased frequency, intensity and duration of extreme heat events Exposure: Pervasive, but differentially affecting some wildlife species depending on their thermal tolerances and occupational groups (e.g. outdoor workers) and those living in high exposure areas (e.g. urban heat islands). Health risks multiply with other harmful exposures, e.g. to wildfire smoke. Vulnerability: Lower adaptive capacity for young/old/sick people, those in low quality housing and lower socio-economic status, and areas served by fragile utilities (power, water). Remote locations with extreme heat and inadequate cooling in housing infrastructure (such as remote indigenous communities). For wildlife, impacts of extreme heat events are being amplified by habitat loss and degradation. Adaptation options: Urban cooling interventions including irrigated green infrastructure and increased albedo, education to reduce heat stress, heatwave/fire early-warning systems, battery/generator systems for energy system security, building standards that improve insulation/cooling, accessible / well-resourced primary health care. For wildlife, removing human stressors, reducing pressures from ferals and weeds, and ensuring there is suitable habitat.
8. Cascading, compounding and	Consequences: Widespread and pervasive damage and disruption to human activities generated by interdependencies and interconnectedness of physical, social and natural

aggregate impacts on cities, settlements, infrastructure, supply-chains and services due to extreme events (*high confidence*) (11.2, 11.3.4, 11.3.5, 11.3.6, 11.3.7, 11.3.8, 11.3.9, 11.3.10, 11.4, 11.5.1, Boxes 11.1, 11.4, 11.6)	systems. Examples include: Failure of transport, energy and communication infrastructure and services, heat-stress, injuries and deaths, air pollution, stress on hospital services, damage to agriculture and tourism, insurance loss from heatwaves and fires; failure of transport, stormwater and flood-control infrastructure and services from floods and storms; water restrictions, reduced agricultural production, stress for rural communities, mental health issues, lack of potable water from droughts; damage to buildings, roads, railways, electricity and water infrastructure, loss of assets and lives, displacement of people, reduced social cohesion, and degraded ecosystems from extreme sea-level rise. Large aggregate costs due to lost productivity and major disaster relief expenditure, creating unfunded liabilities and supply chain disruption, e.g., the 2019-2020 Australian fires cost A$8 billion. The impact of a 1, 2 or 3°C global warming (relative to 1986-2005) on Australian GDP growth is estimated at -0.3%/year, -0.6%/year and -1.1%/year, respectively, while for New Zealand estimates are -0.1%/year, -0.4%/year and -0.8%/year, respectively. Impacts on Māori tribal investments in forestry, agriculture, horticulture, fisheries and aquaculture. Hazards: Heatwaves, droughts, fires, floods, storms and sea-level rise. This includes cascading and compound events such as heatwaves with fires, storms with floods, or droughts followed by heavy rainfall and extreme sea levels. Exposure: Highly populated areas, rural and remote settlements, traditional lands and sacred sites. Greater urban density and population growth increases exposure in high-risk areas. Different exposure for different hazards, e.g. heatwaves: urban and peri-urban areas; fire: peri-urban areas and settlements near forests; floods: people, property and infrastructure from pluvial floods in cities and settlements and fluvial floods on floodplains; storms: buildings and infrastructure in cities and settlements. Vulnerability: Existing social and economic challenges (e.g. those caused by COVID-19) and socio-economic and cultural inequalities; competing resource and land use demands across sectors; inadequate planning, policy, governance, decision making and disaster resilience capacity; and non-climatic stresses on ecosystems. Vulnerabilities generated by interdependencies and interconnectedness of physical, social and natural systems. Adaptation options: Flexible and timely adaptation strategies that prepare socio-economic and natural systems for surprises and unexpected threats. Multi-sector coordinated actions that address widespread impacts, redress existing vulnerabilities and building adaptive capacity and systemic resilience. Improved coordination between and within levels of governments, communities and private sector. Greater use of dynamic decision frameworks and suitable economic and social assessment tools. Improved emergency services and early warning systems; use of climate resilient standards for buildings and infrastructure. Transformational adaptations e.g. managed retreat, that can be planned in stages.
9. Inability of institutions and governance systems to manage climate risks (*high confidence*) (11.2, 11.3.5, 11.3.6, 11.3.7, 11.3.8, 11.3.10, 11.4, 11.5.1, 11.7.2, Boxes 11.1-11.6)	Consequences: Climate hazards overwhelm the capacity of institutions, organisations, systems and leaders to provide necessary policies, services, resources, coordination and leadership. Failed adaptation at the institutional and governance level has widespread, pervasive impacts for all areas of society. This includes a reliance on reactive, short-term decision making that locks in existing exposures, leaves perverse incentives and interconnected and systemic impacts unaddressed, and generates high costs, fiscal impacts. This worsens vulnerability and leads to maladaptation, inequities and injustices within and across generations, as well as actions that do not uphold the rights, interests, values and practices of Indigenous Peoples. Resultant failure to take adaptation action generates litigation risk. Hazards: The increasing frequency, duration, severity and complexity of extreme weather events, droughts and sea-level rise Exposure: All sectors, communities, organisations, and governments Vulnerability: Fragmented institutional and legal arrangements, under-resourcing of services, lack of dedicated adaptation funding instruments and resources to support communities and local government, uneven capability to manage uncertainty, and conflicting values and competing policy and political interests. Adaptation options: Pre-emptive options that avoid and reduce risks. Redesign of policy and statutory frameworks, and funding instruments for addressing changing risks and uncertainties that enable just and collaborative governance across scales and domains. Addressing existing vulnerabilities, and capacity, capability and leadership deficits within

	and across all levels of government, all sectors, Indigenous peoples and communities. Risk and vulnerability assessment methodologies and decision-making tools that build resilience and address changing risks and vulnerabilities. Co-designed adaptation approaches implemented with communities, including Māori tribal organisations and Australian Aboriginal and Torres Strait Island peoples.

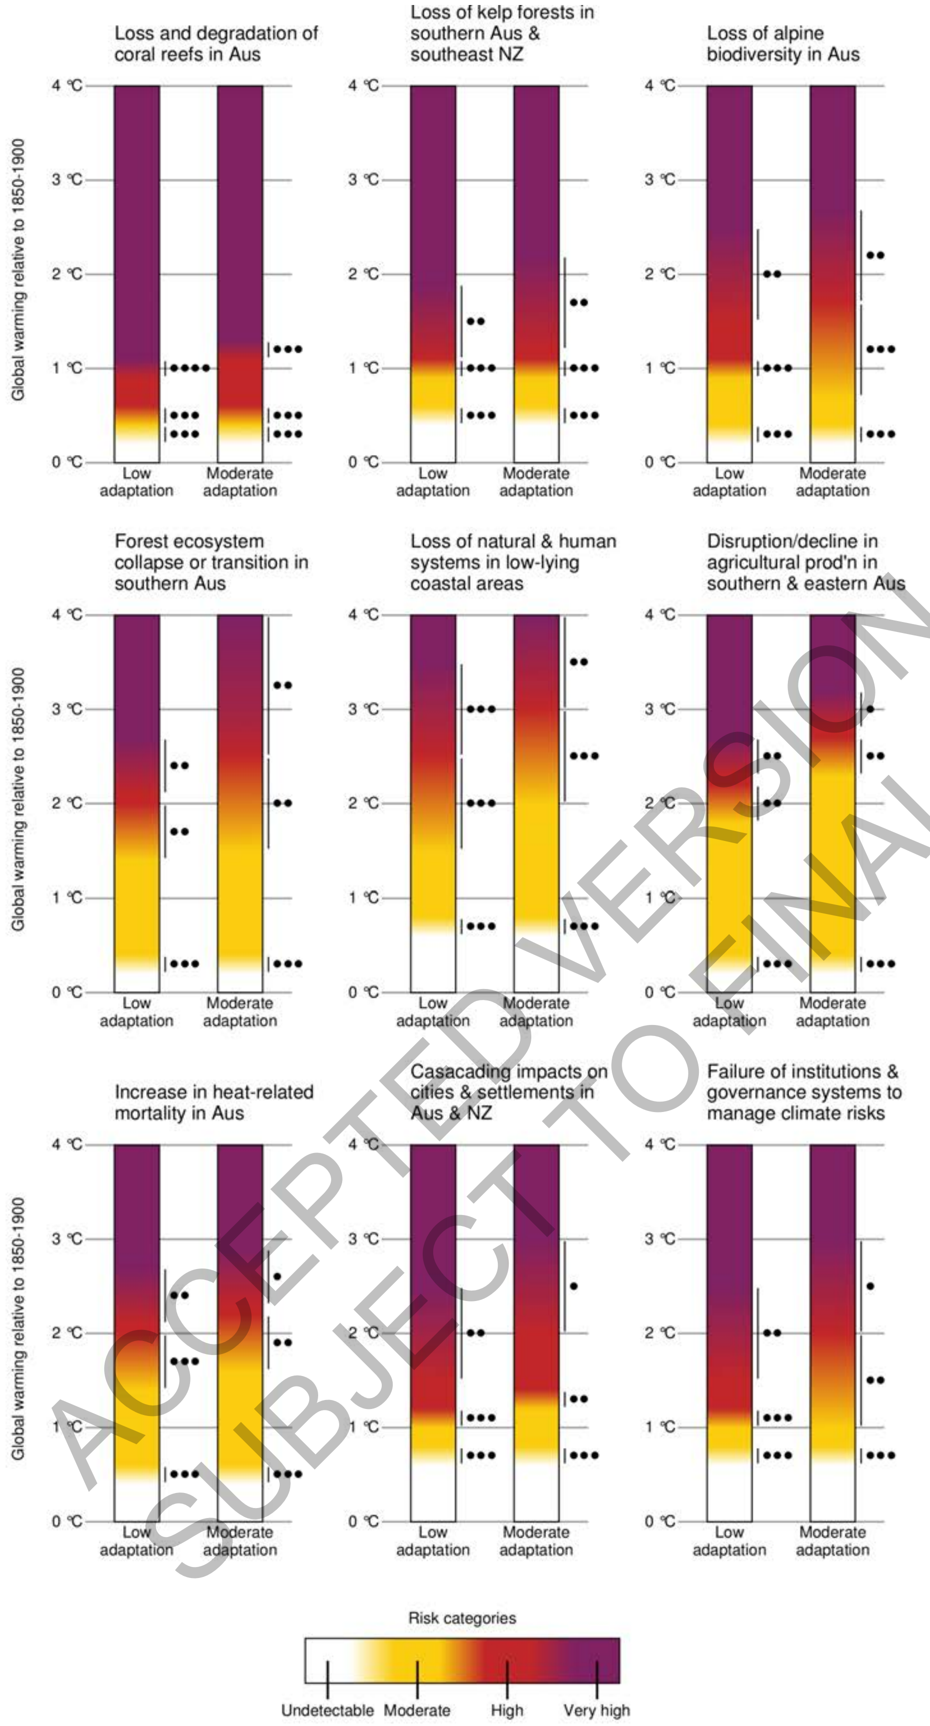

Figure 11.6: Burning embers diagram for each of the nine key risks for low and moderate adaptation. The risk categories are undetectable, moderate, high and very high. While there is no risk category beyond very high, risks obviously get worse with further global warming, and the risk for coral reefs is already very high. The assessment is based on available literature and expert judgement, summarised in Table 11.14 and described in Supplementary Material SM 11.2. The global warming range associated with each risk transition has a confidence rating (**** *very high,* *** *high,* ** *moderate,* * *low*) based on the amount of evidence and level of agreement between lines of evidence.

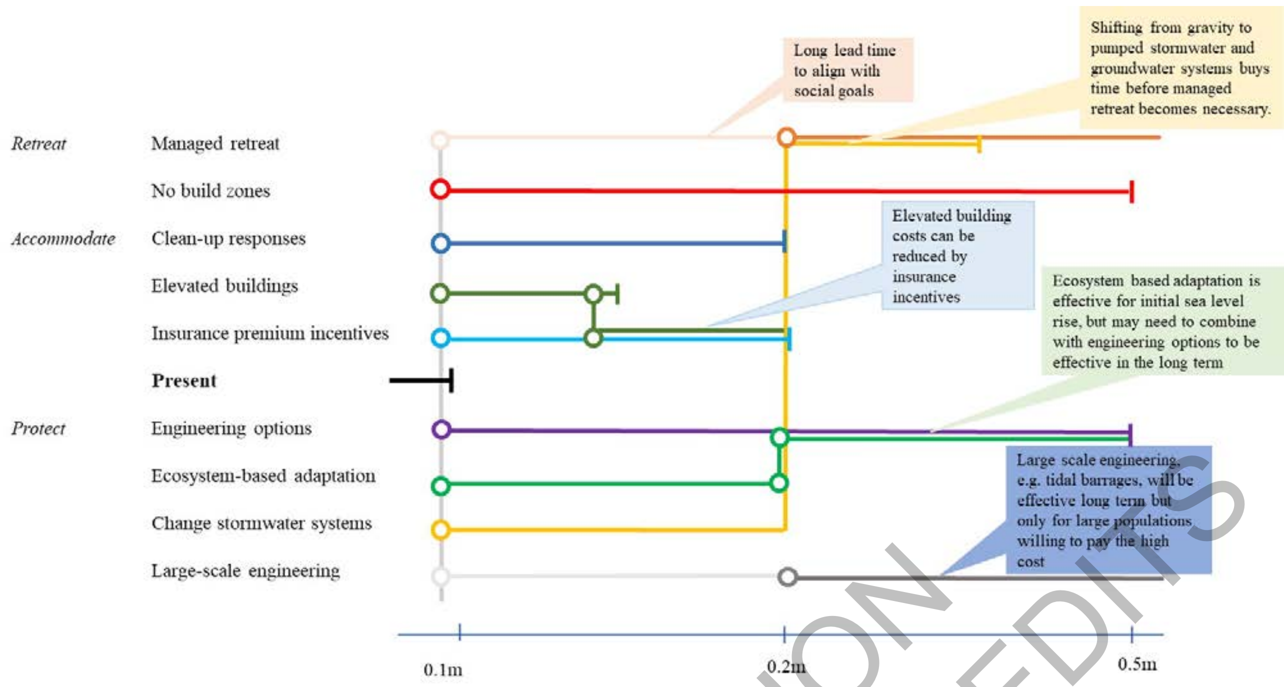

Figure 11.7: Illustrative adaptation pathway for risk to natural and human systems in low-lying coastal areas due to sea-level rise.

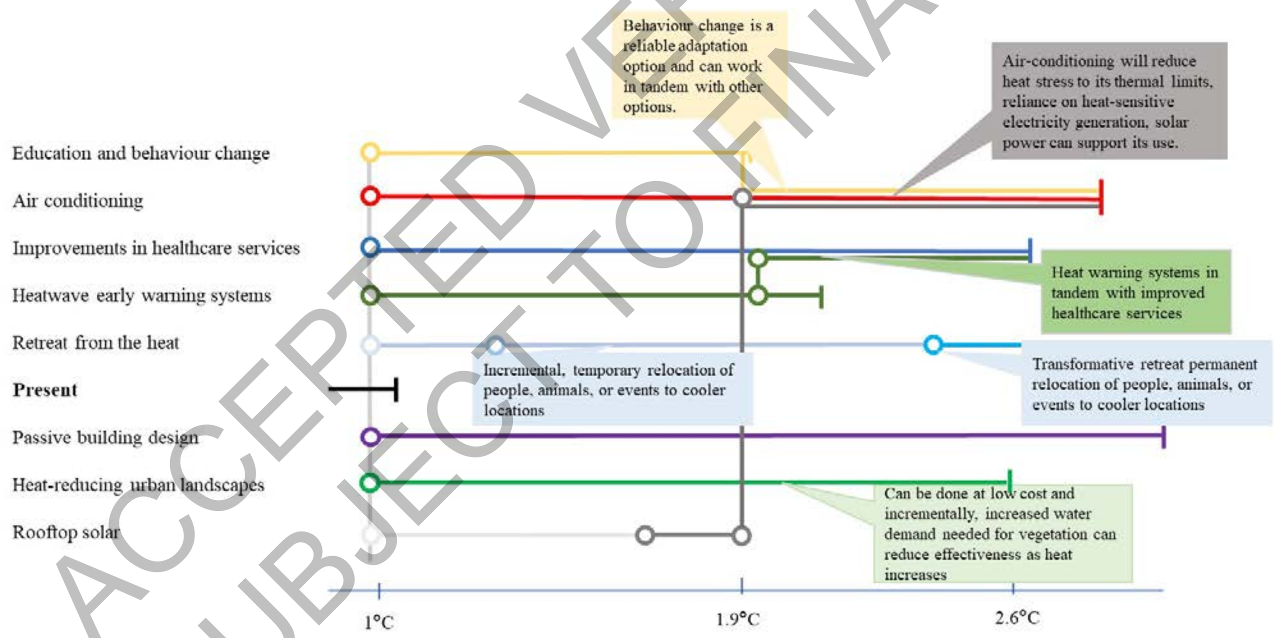

Figure 11.8: Illustrative adaptation pathway for risk of heat-related mortality and morbidity for people and wildlife in Australia due to heatwaves.

11.7 Enabling Adaptation Decision-making

11.7.1 Observed Adaptation Decision-Making

The ambition, scope and progress on adaptation by governments has risen, but is uneven with a focus on high level strategies at national level adaptation planning at sub-national levels and new enabling legislation (Tables 11.15a and 11.15b; (Lawrence et al., 2015; Macintosh et al., 2015; MfE, 2020a) (*very high confidence*). The adaptation process comprises vulnerability and risk assessments, identification of options, planning, implementation, monitoring, evaluation and review. Large gaps remain, especially in effective implementation, monitoring and evaluation (Supplementary Material SM 11.1) (CCATWG, 2017; Warnken and Mosadeghi, 2018) and current adaptation is largely incremental and reactive (Box 11.4, Box 11.6, Table 11.14) (*very high confidence*).

Australia has a National Climate Resilience and Adaptation Strategy, and a National Recovery and Resilience Agency (11.5.2.3), the first National Action Plan to implement the Disaster Risk Reduction Framework acknowledges climate change as a disaster risk driver (Home Affairs, 2020). States and territories have climate change adaptation strategies with plans to address them (Table 11.15a).with some adaptation implementation at state level and increasingly at local government level (Jacobs et al., 2016; Warnken and Mosadeghi, 2018) (Table 11.15a). In coastal zones, however, few local government planning instruments are being applied (Warnken and Mosadeghi, 2018; Harvey, 2019; Robb et al., 2019; Elrick-Barr and Smith, 2021). Some businesses and industry sectors are recognizing climate-related risks and adaptation planning (11.3.4; 11.3.7; 11.3.10) (Harris et al., 2016; Hennessy et al., 2016; CBA, 2019). There is an opportunity for Australia to undertake a national risk assessment and to develop a national climate adaptation implementation plan that is aligned with Paris Agreement expectations of a national level system for adaptation planning, monitoring and reporting (Morgan et al., 2019).

New Zealand's Climate Change Response Act in 2019 creates a legal mandate for National Climate Change Risk Assessments (first one completed) (MfE, 2020a) and National Adaptation Plans (first in preparation) and a Climate Change Commission to monitor and report on adaptation implementation. Preparation of Natural and Built Environment, Strategic Planning and Climate Change Adaptation Acts is underway, including provision for funding and managed retreat (MfE, 2020c). National coastal guidance is available for adaptation planning to address changing climate risks (MfE, 2017a) (Table 11.15b). Meanwhile, several local authorities have developed integrated climate change strategies and plans and revised policies and rules to enable adaptation (Table 11.15b). Different adaptation approaches continue to create confusion and inertia while development pressures continue (Schneider et al., 2017). Opportunities for integrated adaptation and mitigation planning in regional policies and plans have arisen through the Resource Management Amendment Act 2020 (Dickie, 2020), the National Policy Statement on Freshwater Management (MfE, 2020b), and the revised national coastal guidance (MfE, 2017a), but rely on funding instruments to be in place and statutes are aligned for their effectiveness (Boston and Lawrence, 2018; CCATWG, 2018) (*very high confidence*).

There is a growing awareness of the need for more proactive adaptation planning at multiple scales and across sectors, and a better understanding of future risks and limits to adaptation is emerging (Evans et al., 2014; Archie et al., 2018; Christie et al., 2020; MfE, 2020a) (*medium confidence*). Disaster risk reduction is being positioned as part of climate change adaptation (Forino et al., 2017; CDEM, 2019; Forino et al., 2019; CoA, 2020e; CSIRO, 2020). Public and private climate adaptation services are informing climate risk assessments, but are characterized by fragmentation, duplication, inconsistencies, poor governance and inadequate funding - addressing these gaps presents adaptation opportunities (CCATWG, 2018; Webb et al., 2019; NESP ESCC, 2020) (Tables 11.15a; 11.15b). Large infrastructure asset planning is starting to factor in climate risks, but implementation is variable (Gibbs, 2020). Local governments in Australia are increasingly implementing adaptation plans but few monitor or evaluate actual outcomes or know how to (Scott and Moloney, 2021).

Observed and projected rates of sea-level rise (Box 11.6) and increased flood frequency (11.3.3) are challenging established uses of modelling, risk assessment, and cost benefit analysis, where climate change damage functions cannot be projected or are unknown (deep uncertainty), or impacts on communities are ambiguous (Infometrics and PSConsulting, 2015; Lawrence et al., 2019a; MfE, 2020a). New tools are available in the region (Table 11.17) but uptake cannot be assumed (Lawrence and Haasnoot, 2017; Palutikof et al., 2019c) (*high confidence*).

Resilience and adaptation approaches are beginning to converge (White and O'Hare, 2014; Aldunce et al., 2015) (Supplementary Material SM 11.1) but widespread "bounce back" resilience-driven responses that lock in risk by discounting ongoing and changing climate risk (Leitch and Bohensky, 2014; O'Hare et al., 2016; Wenger, 2017; Torabi et al., 2018) can create maladaptation and impede long-term adaptation goals (Glavovic and Smith, 2014; Dudney et al., 2018) (*high confidence*).

Local government engagement with communities on adaptation is starting to motivate a change towards more collaborative engagement practices (Archie et al., 2018; Bendall, 2018; MfE, 2019; Schneider et al., 2020). Nature-based adaptations (Colloff et al., 2016; Lavorel et al., 2019; Della Bosca and Gillespie, 2020) and 'green infrastructure' (Lin et al., 2016; Alexandra and Norman, 2020) are increasingly being adopted (Rogers et al., 2020a) (*medium confidence*).

Some businesses have initiated active adaptation (Aldum et al., 2014; Linnenluecke et al., 2015; Bremer and Linnenluecke, 2017; CCATWG, 2017; MfE, 2018) with most focused on identifying climate risks (Aldum et al., 2014; Gasbarro et al., 2016; Cradock-Henry, 2017). Businesses are more likely to engage in anticipatory adaptation when the frequency of climate events is known (McKnight and Linnenluecke, 2019). Effective cooperation and a positive innovation culture can contribute to the collaborative development of climate change adaptation pathways (Bardsley et al., 2018) (*medium confidence*).

Some areas in northern Australia and New Zealand, especially those with higher proportions of Indigenous populations, face severe housing, health, education, employment and services deficits that exacerbate the impacts of climate change (Kotey, 2015) (11.3.5; 11.4; 11.6). Where adaptation relies upon an aging population and an over-stretched volunteer base, vulnerability to climate change impacts is being exacerbated (Astill and Miller, 2018; Davies et al., 2018). Adaptation options that succeed within remote Indigenous communities are founded on connections to traditional lands, alignment with cultural values and contribute to social, cultural and economic goals (Nursey-Bray and Palmer, 2018). Knowledge co-production for Indigenous adaptation pathways can enable transformative change from colonial legacies (Hill et al., 2020). Learning and experimentation across governance boundaries and between agencies and local communities enables adaptation to be better aligned with changing climate risks and community (Fünfgeld, 2015; Howes et al., 2015; Bardsley and Wiseman, 2016; Lawrence et al., 2019b) (*high confidence*).

There is increasing focus on improving adaptive capacity for transitional and transformational responses, but reactive responses dominate (Smith et al., 2015; Schlosberg et al., 2017; Boston and Lawrence, 2018) (*very high confidence*). While extreme events can provide opportunities for positive transitions within communities (Cradock-Henry et al., 2018b) (for example the Queensland Reconstruction Authority Building Back Better scheme), often rebuilding occurs in at-risk places to aid quick recovery (Lawrence and Saunders, 2017). Community-based adaptation innovations (Kench et al., 2018; Forino et al., 2019){Bendall, 2018 #413} include: relationship building; use of new decision tools, pathways planning with communities, visualisation and serious games (Lawrence and Haasnoot, 2017; Schlosberg et al., 2017; Flood et al., 2018; Reiter et al., 2018; Serrao-Neumann and Choy, 2018); communities of practice; and climate information sharing (Astill et al., 2019; Stone et al., 2019).

Table 11.15a: Examples of Australian adaptation strategies, plans and initiatives by government agencies at the (a) national level, (b) sub-national, and (c) regional or local level. These examples have not been assessed for their effectiveness (see Supplementary Material Table SM11.1a).

Jurisdiction	Strategies/Plans/Actions
New Zealand central Government	The New Zealand Government's adaptation policy framework is based on the following legislation: Resource Management Act 1991; Local Government Act 2002; National Disaster Resilience Strategy 2019 (CDEM, 2019), and the Climate Change Response (Zero Carbon Amendment) Act 2002 (CCRA 2002). Adaptation preparedness report 2020/21 baseline is the reporting organisation responses from the First Information request under the CCRA 2002 (MfE, 2021) to assist the monitoring of progress and effectiveness of adaptation, by the Climate Change Commission The Department of Conservation's Climate Change Adaptation Action plan sets out a long-term strategy for climate research, monitoring, and action. DOC climate adaptation plan
Local Government	In July 2017, a group of 39 Local Government Mayors and Council Chairs (of 78 in total) endorsed a 2015 local government declaration calling for urgent responsive leadership and a holistic approach on climate change, with the government needing to play a vital enabling leadership role (LGNZ, 2017; Schneider et al., 2017). Seventeen councils have declared Climate Emergencies to leverage climate action plans as of September 2021, covering 75.3% of the New Zealand population. The MFE adaptation preparedness report states that 18% of councils (11 of 61 surveyed in 2021) have some sort of plan or strategy to increase resilience to climate impacts (MfE, 2021). Out of New Zealand's 15 regional and unitary councils, two councils have climate adaptation strategies in place. One council has conducted a climate risk assessment. and four have one in development. Five councils have climate action plans and three are in development.
Regional Councils (examples only)	
Bay of Plenty Regional Council	Climate Action Plan July 2019 (non-statutory) Climate Action Plan
Waikato Regional Council	Long Term Plan 2018-2028 (LTP)

Greater Wellington Regional Council	GWRC's Climate Change Strategy (October 2015) Climate change strategy implementation Hutt River Flood Risk Management Plan
Unitary Authorities (examples only)	
Auckland Council	Auckland Unitary Plan AUP RPS B10 Table B11.9- (bottom of doc) E36. Natural hazards and flooding

11.7.2 Barriers and Limits to Adaptation

Major gaps in the adaptation process remain across all sectors and at all levels of decision-making (11.3; Table 11.115a Table 15b) (*very high confidence*). Efforts to build, resource and deploy adaptive capacity are slow compared to escalating impacts and risks (Stephenson et al., 2018; CoA, 2020e). Barriers to effective adaptation include governance inertia at all levels, hindering the development of careful and comprehensive adaptation plans and their implementation (Boston and Lawrence, 2018; MfE and Hawke's Bay Regional Council, 2020; White and Lawrence, 2020). Lack of clarity about mandate, roles and leadership, and inadequate funding for adaptation by national and State governments and sectors, are slowing adaptation (Lukasiewicz et al., 2017; Waters and Barnett, 2018; LGNZ, 2019; MfE, 2020c) (11.3; 11.7.1). Established planning tools and measures were designed for static risk profiles, and practitioners are slow to take up tools better suited to changing climate risks (CoA, 2020e; Schneider et al., 2020) (11.5; Box 11.5). The communication of relevant climate change information remains ad hoc (Stevens and O'Connor, 2015; CCATWG, 2017; Palutikof et al., 2019c; Salmon, 2019). In Australia, the lack of national guidance or adaptation laws create barriers to adaptation, reflected in uneven coastal adaptation based on a "wait and see" approach (Dedekorkut-Howes et al., 2020).

Table 11.16: Examples of barriers to adaptation action in the region

Barrier	Source
Governments Lack of consistent policy direction from higher levels and frequent policy reversals	(Dedekorkut-Howes et al., 2020)
Conflicts between community-based initiatives, City Councils and business interests	(Forino et al., 2019)
Different framings of adaptation between local governments (risk) and community groups (vulnerability, transformation)	(Smith et al., 2015; Schlosberg et al., 2017; McClure and Baker, 2018)
Competing planning objectives	(McClure and Baker, 2018)
Divergent perceptions of risk concepts	(Button and Harvey, 2015; Mills et al., 2016b; Tonmoy et al., 2018)
Focus on climate variability rather than climate change	(Dedekorkut-Howes and Vickers, 2017)

Low prioritization of climate change adaptation among competing institutional objectives	(Glavovic and Smith, 2014; Lawrence et al., 2015; McClure and Baker, 2018)
Constraints in using new knowledge	(Temby et al., 2016)
Lack of institutional and professional capabilities and capacity e.g. to monitor and evaluate adaptation outcomes	(Lawrence et al., 2015; Scott and Moloney, 2021)
Lack of understanding of Indigenous knowledge and practices	(Parsons et al., 2019)
Lack of authority and political legitimacy	(Hayward, 2008; Boston and Lawrence, 2018; CCATWG, 2018; Parsons et al., 2019)
Fear of litigation	(Tombs et al., 2018; Iorns Magallanes and Watts, 2019; O'Donnell et al., 2019)
The upfront costs of adaptation relative to competing demands on government expenditure	(Gawith et al., 2020; Warren-Myers et al., 2020b)
Private sector	
Governance and policy uncertainty, lack of cross sector coordination, lack of capital investment in climate solutions	(CCATWG, 2017; Forino et al., 2017; IGCC, 2021a)
Inconsistent hazard information and incomplete understanding of adaptation	(CCATWG, 2017; Harvey, 2019)
Mismatch in duration of insurance cover (annual) lending (decades) and infrastructure and housing investment (50-100ys)	(Storey and Noy, 2017; O'Donnell, 2020)
Perceived unaffordability of adaptation, lack of client demand and awareness of climate change risks and limited and inconsistent climate risk regulation in the construction industry	(Hurlimann, 2008; Hurlimann et al., 2018)
Translating information into organisations to address disinterest amongst clients in the property industry	(Warren-Myers et al., 2020b; Warren-Myers et al., 2020a)
Erosion of adaptive capacity and challenges of transformational adaptation in agriculture and rural communities	(Jakku et al., 2016)
Communities	
Nature of government engagement with communities	(Public Participation, 2014; MfE, 2017a; Archie et al., 2018; OECD, 2019b)
Lack of clarity regarding roles and responsibilities	(Gorddard et al., 2016; Elrick-Barr et al., 2017; Goode et al., 2017; Waters and Barnett, 2018)
Lack of resourcing of adaptation	(Singh-Peterson et al., 2015; Lukasiewicz et al., 2017; Brookfield and Fitzgerald, 2018)
Lack of deep engagement with climate change	(Kench et al., 2018; Pearce, 2018)
Diverging perceptions, values and goals within communities	(Austin et al., 2018; Fitzgerald et al., 2019; Marshall et al., 2019)
Inequities within and between communities	(Eriksen, 2014; Parkinson, 2019)
Lack of sustained engagement, learning and trust between community, scientists and policy makers	(Serrao-Neumann et al., 2020)

There are many barriers to starting adaptation pre-emptively (CCATWG, 2018) (Table 11.16) (*very high confidence*). Recent institutional changes in New Zealand indicate that this is changing (11.7.1; Table 15b). Many groups are yet to engage deeply with climate change adaptation (Kench et al., 2018) and some adaptation processes are being blocked (Pearce et al., 2018; Garmestani et al., 2019; Alexandra, 2020) or exploited to deflect from mitigation responsibilities (Smith and Lawrence, 2018; Nyberg and Wright, 2020). Some actors are resistant to using climate change information (Tangney and Howes, 2016; Alexandra, 2020). Fear of litigation and demands for compensation can contribute to this reluctance (Tombs et al., 2018; O'Donnell et al., 2019)and is increasingly inviting litigation and other costs (Hodder, 2019; Bell-James and Collins, 2020). Jurisprudence is evolving from cases on projects, to cases about decision making accountability in the public and private sectors (Bell-James and Collins, 2020; Peel et al., 2020) and rights based cases (Peel and Osofsky, 2018). National and sub-national governments may become exposed to unsustainable fiscal risk as insurers of "last resort", which can lead to inequitable outcomes for vulnerable groups and future generations (11.3.8), path dependencies and negative effects on physical, social, economic and cultural systems (Hamin and Gurran, 2015; Boston and Lawrence, 2018). Cross-scale governance tensions can prevent local adaptation initiatives from performing as intended (Tschakert et al., 2016; Piggott-McKellar et al., 2019). Adaptation that draws on Māori cultural understanding in partnership with local government in New Zealand can lead to more effective and equitable adaptation outcomes (MfE, 2020a).

Communities' vulnerabilities are dynamic and uneven (*high confidence*). In Australia, 435,000 people in remote areas face particular challenges (CoA, 2020e). Some groups do not have the time, resources or opportunity to participate in formal adaptation planning as it is currently organised (Victorian Council of Social Service, 2016; Tschakert et al., 2017; Mathew et al., 2018). Linguistically diverse groups can be disadvantaged by social isolation, language barriers, and others' ignorance of the knowledge and skills they can bring to adaptation (Shepherd and van Vuuren, 2014; Dun et al., 2018) (11.1.2). Social, cultural and economic vulnerabilities, biases and injustices, such as those faced by many women (Eriksen, 2014; Parkinson, 2019) and non-heterosexual groups and gender minorities (Dominey-Howes et al., 2016; Gorman-Murray et al., 2017), can deepen impacts and impede adaptation; (Fitzgerald et al., 2019; Marshall et al., 2019) (Cross-Chapter Box GENDER in Chapter 18).

Potential biophysical limits to adaptation for non-human species and ecosystems where impacts are projected to be irreversible, with limited scope for adaptation, are signalled in key risks 1-4 (11.6). In some human systems, fundamental limits to adaptation include thermal thresholds and safe freshwater (Alston et al., 2018) (Table 11.14) and the inability of some low-lying coastal communities to adapt in-place (Box 11.6) (*very high confidence*). Some individuals and communities are already reaching their psycho-social adaptation limits (Evans et al., 2016). A lack of robust and timely adaptation means key risks will increasingly manifest as impacts, and numerous systems, communities and institutions are projected to reach limits (Table 11.14, Figure 11.6), compounding current adaptation deficits and undermining society's capacity to adapt to future impacts (*very high confidence*).

11.7.3 Adaptation enablers

Adaptation enablers include understanding relevant knowledge, diverse values and governance, institutions and resources (Gorddard et al., 2016) (*very high confidence*). Skills and learning, community networks, people-place connections, trust-building, community resources and support and engaged governance build social resilience that support adaptation (Maclean et al., 2014; Eriksen, 2019; Phelps and Kelly, 2019). A multi-faceted focus on the role societal inequalities and environmental degradation play in generating climate change vulnerability can enable fairer adaptation outcomes (McManus et al., 2014; Ambrey et al., 2017; Schlosberg et al., 2017; Graham et al., 2018).

The feasibility and effectiveness of adaptation options will change over time depending on place, values, cultural appropriateness, social acceptability, ongoing cost-effectiveness, leadership and the ability to implement them through the prevailing governance regime (Singh et al., 2020). The capacity and commitment of the political system can drive early action that can reduce risks (Boston, 2017).

Decision makers face the challenge of how to adapt when there are ongoing knowledge gaps, and uncertainties about when some climate change impacts will occur and their scale, e.g. coastal flooding (Box

11.6), or extreme rainfall events and their cascading effects (Box 11.4) (*very high confidence*). No-regrets decisions are *likely* to be insufficient (Hallegatte et al., 2012). A perception exists in some sectors that all climate risks are manageable based on past experience (CCATWG, 2017). Projected impacts, however, are outside the range experienced, meaning that decisions have to be made now for long-lived assets, land uses and communities exposed to the key risks (Paulik et al., 2019a; Paulik et al., 2020) often under contested conditions where adaptation competes with other public expenditure (Kwakkel et al., 2016). New planning approaches being used across the region, can enable more effective adaptation, e.g. continual iterative adaptation (Khan et al., 2015) rapid deployment of decision tools appropriate for addressing uncertainties (Marchau et al., 2019, and transformation of governance and institutional arrangements {Boston, 2018 #444) (Table 11.17). Recognising co-benefits for mitigation and sustainable development can help incentivise adaptation (11.3.5.3, 11.8.2).

Table 11.17: Key enablers for adaptation

Enabler	Example
Governance frameworks	Clear climate change adaptation mandate Measures that inform a shift from reactive to anticipatory decision making, e.g. decision tools that have long timeframes Institutional frameworks integrated across all levels of government for better coordination Revised design standards for buildings, infrastructure, landscape such as common land use planning guidance and codes of practice that integrate consideration of climate risks to address existing and future exposures and vulnerability of people, physical and cultural assets (11.3.1, 11.3.2, 11.3.3, 11.3.4.3, 11.3.5, 1.3.6, 11.4.1, 11.4.2, 11.5.1, 11.5.2, 11.6, 11.7.1, 11.7.2, 11.8.1, 11.8.2, Table 11.7, Table 11.14, Box 11.1, Box 11.3, Box 11.5, Box 11.6)
Building capacity for adaptation	Provision of nationally consistent risk information through agreed methodologies for risk assessment that address non-stationarity Targeted research including understanding the projected scope and scale of cascading and compounding risks Education, training and professional development for adaptation under changing risk conditions Accessible adaptation tools and information (11.1.2, 11.3.4, 11.3.5, 11.4.1, 11.5.1, 11.6, 11.7.1, 11.7.2, Table 11.14, Table 11.16, Table 11.18, Box 11.6)
Community partnership and collaborative engagement	Community engagement based on principles that consider social and cultural and Indigenous Peoples' contexts and an understanding of what people value and wish to protect, e.g. International Association of Public Participation (Public Participation, 2014). Use of collaborative and learning-oriented engagement approaches tailored for the social and informed by the cultural context Community awareness and network building Building on Indigenous Australian and Māori communities' social-cultural networks and conventions that promote collective action and mutual support (11.3.5, 11.4, 11.7.1, 11.7.3.2, Table Box 11.1.1, Table 11.14, Box 11.6)
Dynamic adaptive decision-making	Increased understanding and use of decision-making tools to address uncertainties and changing risks, such as scenario planning and dynamic adaptive pathways planning to enable effective adaptation as climate risk profiles worsen (11.7.3.1, 11.7.3.2, Table 11.14, Table 15b, Table 11.18, Box 11.4, Box 11.6)
Funding mechanisms	Adaptation funding framework to increase investment in adaptation actions New private sector financial instruments to support adaptation (11.7.1, 11.7.2, Table 11.16)
Reducing systemic vulnerabilities	Economic and social policies that reduce income and wealth inequalities Strengthening social capital and cohesion Identifying and redressing rigid or fragmented administrative and service delivery systems Review of land use and spatial planning to reduce exposure to climate risks Restoring degraded ecosystems and avoiding further environmental degradation and loss. (11.1.1,11.1.2,11.3.5, 11.3.11, 11.4.1, 11.5.1.3, 11.7.2, 11.8.1, Table 11.10, Table 11.13)

11.7.3.1 Planning and Tools

Adaptation decision support tools enable a shift from reactive to anticipatory planning for changing climate risks (*high confidence)*. The available tools are diversifying with futures and systems methodologies and dynamic adaptive policy pathways being increasingly used (Bosomworth et al., 2017; Prober et al., 2017; Lawrence et al., 2018a; CoA, 2020e; Rogers et al., 2020a; Schneider et al., 2020) (11.5; Box 11.6) to help shift from static to dynamic adaptation by highlighting path dependencies and potential lock in of decisions, system dependencies and the potential for cascading impacts (Table 11.17) (Wilson et al., 2013; Clarvis et al., 2015; Pearson et al., 2018; Cradock-Henry et al., 2020b; Lawrence et al., 2020b). Modelling and tools to test the robustness and cost-effectiveness of options (Infometrics and PSConsulting, 2015; Qin and Stewart, 2020) can be used alongside adaptation strategies with decision-relevant and usable information (Smith et al., 2016; Tangney, 2019; Serrao-Neumann et al., 2020), particularly when supported by effective governance and national and sub-national guidance (Box 11.6).

More inclusive, collaborative and learning-oriented community engagement processes are fundamental to effective adaptation outcomes (11.7.3.2) (Boston, 2016; Lawrence and Haasnoot, 2017; Sellberg et al., 2018; Serrao-Neumann et al., 2019a; Simon et al., 2020) (*very high confidence*). More participatory vulnerability and risk assessments can better reflect different knowledge systems, values, perspectives, trade-offs, dilemmas, synergies, costs and risks (Jacobs et al., 2019; Ogier et al., 2020; Tonmoy et al., 2020). A shift from hierarchical to more cooperative governance modalities can assist effective adaptation (Vermeulen et al., 2018; Steffen et al., 2019; CoA, 2020e; Lawrence et al., 2020b; MfE, 2020a; Hanna et al., 2021).

Regular monitoring, evaluation, communication and coordination of adaptation are essential for accelerating learning and adjusting to dynamic climate impacts and socio-economic and cultural conditions change (Moloney and McClaren, 2018; Palutikof et al., 2019a; Cradock-Henry et al., 2020a) (*high confidence*). Training to improve decision-makers' 'evaluative capacity' can play a role (Scott and Moloney, 2021). Climate action benchmarking, diagnostic tools and networking can enhance the adaptation process across diverse decision settings e.g. water, coasts, protected areas and Indigenous Peoples (Ayre and Nettle, 2017; Davidson and Gleeson, 2018; Coenen et al., 2019; Gibbs, 2020). Effective adaptation requires cross-jurisdictional and cross-sectoral policy coherence and national coordination (Delany-Crowe et al., 2019; Rychetnik et al., 2019; MfE, 2020c).

Table 11.18: Examples of adaptation decision tools

Tools	Application	Source
Scenario analysis, modelling, futures narratives	For futures planning in coastal, urban, agriculture and health sectors	(Randall et al., 2012; Jones et al., 2013; CSIRO, 2014; Bosomworth et al., 2015; Infometrics and PSConsulting, 2015; Knight-Lenihan, 2016; Maier et al., 2016; Stephens et al., 2017; B. Frame et al., 2018; Stephens et al., 2018; Ausseil et al., 2019a; Coulter et al., 2019; Serrao-Neumann et al., 2019b)
Dynamic Adaptive Pathways Planning (DAPP)	For conditions of deep uncertainty for short-term and long-term options and flexibility, and with communities	(Cradock-Henry et al., 2018b; Cradock-Henry et al., 2020a) (agriculture); (Lawrence et al., 2019b) (flood risk management) (Lawrence and Haasnoot, 2017; Colliar and Blackett, 2018) (coastal communities) (Tasmanian Climate Change Office, 2012; Lin et al., 2017; Ramm et al., 2018) (capacity building) (Moran et al., 2014; Colloff et al., 2016; Dunlop et al., 2016; Bosomworth et al., 2017) (natural resource, management) (Hadwen et al., 2012; Barnett et al., 2014b; Fazey et al., 2015; Lazarow, 2017; Ramm et al., 2018) (coastal) (Siebentritt et al., 2014; Zografos et al., 2016) (regional development)

		(Maru et al., 2014) (disadvantaged communities) (Hertzler et al., 2013; Sanderson et al., 2015) (agriculture) (Ren et al., 2011) (infrastructure and resilient cities) (Cunningham et al., 2017) (social network analysis with communities)
Serious Games	To catalyse learning, raise awareness and explore attitudes and values	(Lawrence and Haasnoot, 2017; Colliar and Blackett, 2018; Flood et al., 2018; Edwards et al., 2019)
Signals and Triggers for monitoring DAPP	For where there is near-term certainty and longer-term deep uncertainty e.g. sea-level rise	(Stephens et al., 2017; Stephens et al., 2018)
Shared Socio-economic Pathways	For where there is deep uncertainty and scenarios are used	(B. Frame et al., 2018)
Hybrid Multi-criteria analysis and DAPP (deep uncertainty)	For conditions of deep uncertainty for short-term and long-term options and flexibility desired	(D. Frame et al., 2018; Lawrence et al., 2019a)
Real Options Analysis (ROA)	For conditions of deep uncertainty	(Infometrics and PSConsulting, 2015; Infometrics, 2017; Lawrence et al., 2019a; Wreford et al., 2020)
Scenario-based cost-benefit analysis	For conditions of deep uncertainty	(Guthrie, 2019)
Portfolio analysis	For uncertainties in the land use sector	(Monge et al., 2016; Awatere et al., 2018)(West et al. 2021)
Cost Benefit Analysis	Where decisions can be easily reversed	(Hadwen et al., 2012; Little and Lin, 2015; Stewart, 2015; Luo et al., 2017; Thamo et al., 2017)
Vulnerability assessment	For assessing and prioritising physical and social place-based risks, using indices, modelling and participatory approaches	(Ramm et al., 2017; Moglia et al., 2018; Pearce et al., 2018; Tonmoy and El-Zein, 2018)
Statutory tools	For planning direction	(DoC NZ, 2010; DoC NZ, 2017a; DoC NZ, 2017b; NSW Government, 2018)
	For planning and design of adaptation	(MfE, 2017a)
Standards	For adaptation best practice	(ISO, 2019)
Jurisprudence	For adaptation implementation and legal interpretation	(O'Donnell and Gates, 2013; McAdam, 2015; Iorns Magallanes and Watts, 2019; Peel et al., 2020)
Guidance	For adaptation and use of uncertainty tools	(CSIRO and BOM, 2015; MfE, 2017a; Lawrence et al., 2018b; Palutikof et al., 2019b)
Information delivery and decision support portal	For adaptation decision making	https://coastadapt.com.au/

Monitoring, evaluation and reporting on adaptation progress (incl. adaptation indices and web-based tools)	For local government, private sector and finance sector to benchmark, track progress	(Goodhue et al., 2012; Little et al., 2015; IGCC, 2017; Lawrence et al., 2020a; LGAQ and DES, 2020; Rogers et al., 2020b; WAGA, 2020) (Moloney and McClaren, 2018)

11.7.3.2 Attitudes, Engagement and Accessible Information as Enablers

Concern for climate change has become widespread (Hopkins, 2015; Borchers Arriagada et al., 2020), giving climate adaptation social legitimacy (*high confidence*). Over three quarters of Australians (77%) agree that climate change is occurring and 61% believe climate change is caused by humans (Merzian et al., 2019). A growing proportion of Australians perceive links between climate change and high temperatures experienced during heatwaves and extremely hot days (2018/2019 Summer) (48%), droughts and flooding (42%), and urban water shortages (30%) (Merzian et al., 2019). Rural populations in NSW perceive climate change impacts as stressing their wellbeing and mental health and requiring leadership and action (Austin et al., 2020). In New Zealand, between 2009 and 2018, the proportion of New Zealanders who agreed or strongly agreed that climate change is real increased from 58% to 78% (a 34.5% increase), while those agreeing or strongly agreeing with human causation increased from 41% to 64% (a 56.1% increase) (Milfont et al., 2021). Nevertheless, New Zealanders have a tendency to overestimate the amount of sea-level rise, especially amongst those most concerned about climate change, and incorrectly associate it with melting sea ice, which has implications for engagement and communication strategies (Priestley et al., 2021).

Use of more systemic, collaborative and future-oriented engagement approaches is facilitating adaptation in local contexts (Rouse et al., 2013; MfE, 2017a; Leitch et al., 2019) (*high confidence*). Local 'adaptation champions' and experimental and tailored engagement processes can enhance learning (McFadgen and Huitema, 2017; Lindsay et al., 2019). Dynamic adaptive pathways planning (Lawrence et al., 2019a) and inclusive community governance (Schneider et al., 2020)can help progress difficult decisions such as the relocation of cultural assets and managed retreat, and contestation about which public goods to prioritise and how adaptation should be implemented (Kwakkel et al., 2016) (Colliar and Blackett, 2018). Participatory climate change scenario planning can test assumptions about the present and the future (Mitchell et al., 2017; Serrao-Neumann and Choy, 2018; Chambers et al., 2019; Serrao-Neumann et al., 2019c) and help envision people-centred, place-based adaptation (Barnett et al., 2014b; Lindsay et al., 2019). Social network analysis can inform engagement and communication of adaptation (Cunningham et al., 2017). Knowledge brokers, information portals and alliances can help communities, governments and sector groups to better access and use climate change information (Shaw et al., 2013; Fünfgeld, 2015; Lawrence and Haasnoot, 2017). Novel approaches to building climate change literacy and adaptation capability go hand in hand with dedicated expert organisational support (Stevens and O'Connor, 2015; CCATWG, 2018; Palutikof et al., 2019c; Salmon, 2019). All of these approaches depend on adequate resourcing (*very high confidence*).

11.7.3.3 Knowledge Gaps and Implementation Enablers

There are two priority areas where new knowledge is critical for accelerating adaptation implementation.

1) *System complexity and uncertainty in observed and projected impacts*
- Regionally relevant projections of rainfall, runoff, compound and extreme weather (11.2.1; 11.3.3; Box 11.4).
- Inclusion of cascading and compounding impacts in integrated assessments (11.5.1) including for infrastructure (11.3.5), tourism (11.3.7) and health (11.3.6) and for different groups, including Aboriginal and Torres Strait Islander Peoples and Tangata Whenua Māori communities (11.4).
- Impacts on terrestrial and freshwater ecosystems, including in-situ monitoring to detect ongoing changes especially in New Zealand (11.3.1), and marine biodiversity including environmental tolerances of key life stages (11.3.2).
- Repository of indigenous species distribution data for monitoring responses to climate change and climate advisory services for New Zealand (11.3.1.3).

- National risk assessment for Australia (11.7.1).
- The interactions between adaptation and mitigation, particularly where land carbon mitigation is impacted by climate change (11.3.4.3; Box 11.5).

2) *Supporting adaptation decision making*

- Better understanding of who and what is exposed and where, and their vulnerability to climate hazards (11.3, 11.4).
- National assessments of the costs and benefits of climate change, with and without different levels and timings of adaptation and mitigation (11.5.2.3) (11.7.1).
- Understanding available adaptation strategies and options, their feasibility and effectiveness as the climate changes, including their intended and unintended outcomes (11.7, 11.8).
- Understanding how to embed robust planning approaches into decision making that retain flexibility to change course in the future (11.7.1).
- Mechanisms for sharing knowledge and practice of adaptation (11.7).
- The role of development paradigms, values and political economy in adaptation framing and effective implementation (11.8).
- Understanding social transitions and social licence, for timely, robust and transformational adaptation (11.8.2).

11.8 Climate Resilient Development Pathways

Adaptation to climate risks and global mitigation of greenhouse emissions determine whether development pathways are climate resilient (Chapter 18). In the near-term, progress towards climate resilient development can be monitored by progress on the Sustainable Development Goals (SDGs). According to government reports (OECD, 2019a) (Figure 11.6) current and projected trajectories fall short of meeting all targets (Allen et al., 2019). Key climate risks for the region (11.6, Table 11.14) affect all of the SDGs, and pre-existing societal inequalities exacerbate climate risks (11.3.5). Projected climate risks combined with underlying SDG indicators will increasingly impede the region's capacity to achieve and maintain a number of SDGs, including sustainable agriculture, affordable and clean energy, sustainable cities and communities, life below water and life on land (OECD, 2019a). Reducing these risks would require significant and rapid emission reductions to keep global warming to 1.5-2.0°C, and robust and timely adaptation (IPCC, 2018).

11.8.1 System Adaptations and Transitions

A step-change in adaptation action is needed to address climate risks and to be consistent with climate resilient development *(very high confidence).* Current adaptation falls short on assessment of complex risks, implementation, monitoring, and evaluation. It is largely incremental and temporary given the scale of projected impacts, it has limits and is mainly reactive rather than anticipatory. Furthermore, risks are projected to cascade and compound, with impacts and costs that challenge adaptive capacities (11.5) and call for transformational responses (11.6, Table 11.15a; Table 11.15b; Supplementary Tables SM11.1a; SM11.1b).

Current global emissions reduction policies are projected to lead to a global warming of 2.1-3.9 °C by 2100 (Liu and Raftery, 2021), leaving many of the region's human and natural systems at very high risk and beyond adaptation limits (*high confidence*). With higher levels of warming, adaptation costs increase, loss and damages grow, and governance and institutional responses have reduced adaptive capacity. Underlying social and economic vulnerabilities and injustices further reduce adaptive capacity, exacerbating disadvantage in particular groups in society. Sustainable development across and beyond the region will help reduce shared adaptation challenges (11.5.1.2). Effective adaptation avoids lock-in and path dependency, reduces vulnerabilities, increases flexibility to change, builds adaptive capacity and progresses SDGs, thus improving intra- and inter-generational justice (11.5, 11.6, 11.7). Reducing greenhouse gas emissions and structural inequalities is key to achieving the SDGs and contributing to climate resilient development.

Integrated and inclusive adaptation decision making can contribute to climate resilient development by better mediating competing values, interests and priorities and helping to reconcile short-and long-term objectives, as well as public and private costs and benefits, in the face of rapidly and continuously changing risk profiles

(Gorddard et al., 2016; MfE, 2017a; Schlosberg et al., 2017) (11.5.2) *(very high confidence).* Use of new tools and approaches (Table 11.18) to address system interactions that match the scale and scope of the problem can result in more effective adaptation, including proactive and anticipatory governance and institutional enablers (11.7, Table 11.17) (Schlosberg et al., 2017; Boston and Lawrence, 2018). Building cities and settlements that are resilient to the impacts of climate change requires the simultaneous consideration of infrastructural, ecological, social, economic, institutional, and political dimensions of resilience including political will, leadership, commitment, community support, multilevel governance, and policy continuity (Torabi et al., 2021).

11.8.2 Challenges for Climate Resilient Development Pathways

Implementing enablers can help drive adaptation ambition and action consistent with climate resilient development (11.7.3, Table 11.17) (*very high confidence*). However, the scale and scope of cascading, compounding and aggregate impacts (11.5.1) calls for new and timely adaptation, including more effective ongoing monitoring, evaluation, review and continual adjustment (11.7.3) towards the transformations that can break through the 'path dependencies' that define the way things are done now (Cradock-Henry et al., 2018b; UN et al., 2018; Head, 2020). However, complex interactions between objectives can create social and economic trade-offs (Table 11.1, 11.3.5.3, 11.7.3.1, Box 11.6).

Delay in implementing climate change adaptation and emissions reductions will impede climate resilient development, resulting in more costly climate impacts and greater scale of adjustments in the future (IPCC, 2018) (11.5.1; 11.5.2) (Box 11.6) and legal risks for those with adaptation mandates and for financial institutions (11.5.1) (*very high confidence*). The scale and scope of societal change needed for the region to transition to more climate resilient development pathways requires close attention to governance, ethical questions, the role of civil society, the place of Aboriginal and Torres Strait Islander Peoples and Tangata Whenua Māori in the co-production of ongoing adaptation at multiple scales (Koehler et al., 2017; Loorbach et al., 2017; Hill et al., 2020).

The region faces an extremely challenging future that will be highly disruptive for many human and natural systems (IPCC, 2018) (UNEP, 2020; AAS, 2021; IPCC, 2021) (11.5.1; 11.6; 11.7) (Box 11.1-11.6) (Table 11.14). The extent to which the limits to adaptation are reached depends on whether global warming peaks this century at 1.5, 2 or 3+°C above pre-industrial levels. Whatever the outcome, adaptation and mitigation are essential and urgent. (*very high confidence*)

[START FAQ11.1 HERE]

FAQ 11.1: How is climate change affecting Australia and New Zealand?

Climate change is affecting Australia and New Zealand significantly. Some natural systems of cultural, environmental, social and economic significance are at risk of irreversible change. The socio-economic costs of climate change are substantial, with impacts that cascade and compound across sectors and regions, as demonstrated by heatwaves, wildfire, cyclone, drought and flood events.

Temperature has increased by 1.4°C in Australia and 1.1°C in New Zealand over the last 110 years, with more extreme hot days. The oceans in the region have warmed significantly, resulting in longer and more frequent marine heatwaves. Sea levels have risen and the oceans have become more acidic. Snow depths have declined and glaciers have receded. North-western Australia and most of southern New Zealand have become wetter, while southern Australia and most of northern New Zealand have become drier. The frequency, severity and duration of extreme wildfire weather conditions has increased in southern and eastern Australia and north-eastern New Zealand.

The impacts of climate change on marine, terrestrial and freshwater ecosystems and species are evident. The mass mortality of corals throughout the Great Barrier Reef during marine heatwaves in 2016–2020 is a striking example. Climate change has contributed to the unprecedented south-eastern Australia wildfires in the spring-summer of 2019–2020, loss of alpine habitats in Australia, extensive loss of kelp forests, shifts further south in the distribution of almost 200 marine species, decline and extinction in some vertebrate species in the Australian wet tropics, expansion of invasive plants, animals and pathogens in New Zealand, erosion and flooding of coastal habitats in New Zealand, river flow decline in southern Australia, increased stress in rural communities, insurance losses for floods in New Zealand, increase in heat wave mortalities in Australian capital cities, and the fish deaths in Murray-Darling River in the summer of 2018–2019.

[END FAQ11.1 HERE]

[START FAQ11.2 HERE]

FAQ 11.2: What systems in Australia and New Zealand are most at risk from ongoing climate change?

The nine key risks to human systems and ecosystems in Australia and New Zealand from ongoing climate change are shown in Figure FAQ 11.2.1. Some risks, especially on ecosystems, are now difficult to avoid. Other risks can be reduced by adaptation, if global mitigation is effective.

Risk is the combination of hazard, exposure and vulnerability. For a given hazard (e.g. fire), the risk will be greater in areas with high exposure (e.g. many houses) and/or high vulnerability (e.g. remote communities with limited escape routes). The severity and type of climate risk varies geographically (Figure FAQ 11.2.1). Everyone will be affected by climate change, with disadvantaged and remote people and communities the most vulnerable.

The risks to natural and human systems are often compounded by impacts across multiple spatial and temporal scales. For example, fires damage property, farms, forests and nature with short- and long-term effects on biodiversity, natural resources, human health, communities and the economy. Major impacts across multiple sectors can disrupt supply chains to industries and communities and constrain delivery of health, energy, water and food services. These impacts create challenges for adaptation and governance of climate risks. When combined, these have far-reaching socio-economic and environmental impacts.

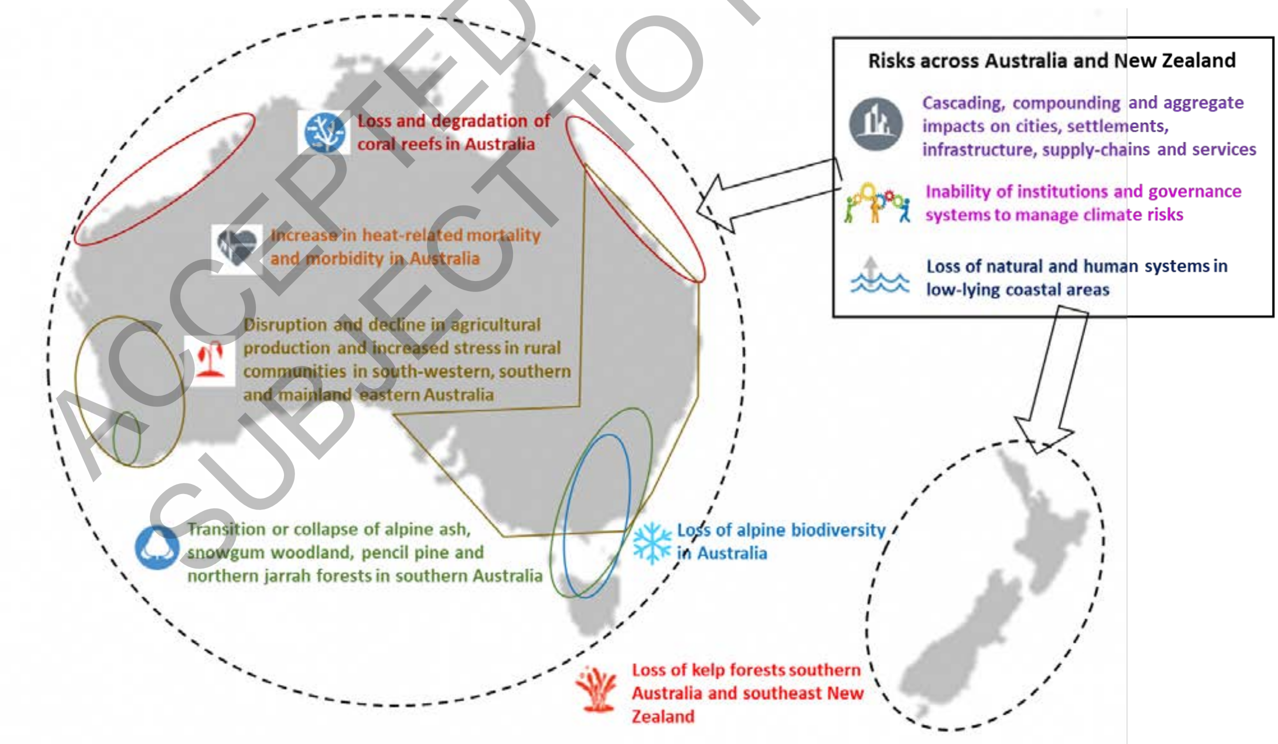

Figure FAQ 11.2.1: Key risks from climate change

[END FAQ11.2 HERE]

[START FAQ11.3 HERE]

FAQ 11.3: How can Indigenous Peoples' knowledge and practice help us understand contemporary climate impacts and inform adaptation in Australia and New Zealand?

In Australia and New Zealand, as with many places around the world, Indigenous Peoples with connections to their traditional country and extensive histories, hold deep knowledge from observing and living in a changing climate. This provides insights that inform adaptation to climate change.

Indigenous Australians - Aboriginal and Torres Strait Islanders - maintain knowledge regarding previous sea-level rise, climate patterns, and shifts in seasonal change associated with flowering of trees and emergence of food sources, developed over thousands of generations of observation of their traditional country. Knowledge of localised contemporary adaptation is also held by many Indigenous Australians with connections to traditional lands. With assured Free and Prior-Informed Consent, this provides a means for Indigenous-guided land management, including for fire management and carbon abatement, fauna studies, medicinal plant products, threatened species recovery, water management, and weed management.

Tangata Whenua Māori in New Zealand are grounded in Mātauranga Māori knowledge which is based on human-nature relationships and ecological integrity and incorporates practices used to detect and anticipate changes taking place in the environment. Social-cultural networks and conventions that promote collective action and mutual support are central features of many Māori communities and these customary approaches are critical to responding to, and recovering from, adverse environmental conditions. Intergenerational approaches to planning for the future are also intrinsic to Māori social-cultural organisation and are expected to become increasingly important, elevating political discussions about conceptions of rationality, diversity and the rights of non-human entities in climate change policy and adaptation.

[END FAQ11.3 HERE]

[START FAQ11.4 HERE]

FAQ 11.4: How can Australia and New Zealand adapt to climate change?

There is already work underway by governments, businesses, communities and Indigenous Peoples to help us adapt to climate change. However, much more adaptation is needed for the ongoing and intensifying climate risks. This includes coordinated laws, plans, guidance and funding that enable society to adapt, and the information, education and training that can support it. Everyone has a role to play, working together.

We currently mainly react to climate events such as wildfires, heatwaves, floods and droughts, and generally rebuild in the same places. However, climate change is making these events more frequent and intense, and ongoing sea-level rise and changes in natural ecosystems are advancing. Better coordination and collaboration between government agencies, communities, Aboriginal and Torres Strait Islanders and Tangata Whenua Indigenous Peoples, not-for-profit organisations and businesses will help prepare for these climate impacts more proactively, in combination with future climate risks integrated into their decisions and planning. This will reduce the impacts we experience now and the risks that will affect future generations.

Some of the risks for natural systems are close to critical thresholds and adaptation may be unable to prevent ecosystem collapse. Other risks will be severe, but we can reduce their impact by acting now, for example coastal flooding from sea-level rise, heat-related mortality and managing water stresses. Many of the risks have potential to cascade across social and economic sectors with widespread societal impacts. In such cases, really significant system-wide changes will be needed to the way we live and govern currently. To facilitate such change, new governance frameworks, nationally consistent and accessible information, collaborative engagement and partnerships with all sectors, communities and Indigenous Peoples and the resources to address the risks, are needed (Figure FAQ 11.4.1).

However, our ability to adapt to climate change impacts also rests on every region in the world playing its part in reducing greenhouse gas emissions. If mitigation is ineffective, global warming will be rapid, adaptation costs will increase, with worsening losses and damages.

Executive Summary

Vulnerability and observed impacts:

Central and South America are highly exposed, vulnerable and strongly impacted by climate change, a situation amplified by inequality, poverty, population growth and high population density, land use change particularly deforestation with the consequent biodiversity loss, soil degradation, and high dependence of national and local economies on natural resources for production of commodities (*high confidence*[1]). Profound economic, ethnic and social inequalities are exacerbated by climate change. High levels of widespread poverty, weak water governance, unequal access to safe water and sanitation services and lack of infrastructure and financing reduce adaptation capacity, increasing and creating new population vulnerabilities (*high confidence*). {12.1.1, 12.2, 12.3, 12.5.5, 12.5.7, Figure 12.2}

The Amazon forest, one of the world's largest biodiversity and carbon repositories, is highly vulnerable to drought (*high confidence*). The Amazon forest was highly impacted by the unprecedented droughts and higher temperatures observed in 1998, 2005, 2010 and 2015/2016 attributed partly to climate change. This resulted in high tree mortality rates and basin-wide reductions in forest productivity, momentarily turning pristine forest areas from a carbon sink into a net source of carbon to the atmosphere (*high confidence*). Other terrestrial ecosystems in Central and South America have been impacted by climate change, through persistent drought or extreme climatic events. The combined effect of anthropogenic land use change and climate change increases the vulnerabilities of terrestrial ecosystems to extreme climate events and fires (*medium confidence*). {12.3, 12.4, Figure 12.7, Figure 12.9, Figure 12.10}

The distribution of terrestrial species has changed in the Andes due to increasing temperature (*very high confidence*). Species have shifted upslope leading to range contractions for highland species, and range contractions and expansions for lowland species, including crops and vectors of diseases (*very high confidence*). {12.3.2.4}

Ocean and coastal ecosystems in the region such as coral reefs, estuaries, salt marshes, mangroves and sandy beaches are highly sensitive and negatively impacted by climate change and derived-hazards (*high confidence*). Observed impacts include the reduction in coral abundance, density and cover in Central America, Northwest South America and Northeast South America and increasing number of coral bleaching events in Central America and Northeast South America; changes in the plankton community and in ocean and coastal food web structures, loss of vegetated wetlands and changes in macrobenthic communities in Central America, Northwest, Northern, and Southeast South America. {12.3, 12.5.2, Figure 12.8, Figure 12.9, Table SM12.3}

Global warming has caused glacier loss in the Andes from 30% to more than 50% of their area since the 1980s. Glacier retreat, temperature increase and precipitation variability, together with land-use change, have affected ecosystems, water resources, and livelihoods through landslides and flood disasters (*very high confidence*). In several areas of the Andes, flood and landslide disasters have increased, and water availability and quality and soil erosion have been affected by both climatic and non-climatic factors (*high confidence*). {12.3.2, 12.3.7, Figure 12.9, Figure 12.13, Table SM12.6}

The scientific evidence since the IPCC AR5 increased the confidence on the synergy among fire, land use change, particularly deforestation, and climate change, directly impacting human health, ecosystem functioning, forest structure, food security and the livelihoods of resource-dependent communities (*medium confidence*). Regional increase in temperature, aridity and drought increased the frequency and intensity of fire. On average, people in the region were more exposed to high fire danger between 1 and 26 additional days depending on the subregion for the years 2017-2020 compared to 2001-2004 (*high confidence*). {12.2, 12.3, Figure 12.9, Figure 12.10, Table 12.5}

[1] In this Report, the following summary terms are used to describe the available evidence: limited, medium, or robust; and for the degree of agreement: low, medium, or high. A level of confidence is expressed using five qualifiers: very low, low, medium, high, and very high, and typeset in italics, e.g., *medium confidence*. For a given evidence and agreement statement, different confidence levels can be assigned, but increasing levels of evidence and degrees of agreement are correlated with increasing confidence.

Changes in timing and magnitude of precipitation and extreme temperatures are impacting agricultural production (*high confidence*). Since the mid-20th century, increasing mean precipitation has positively impacted agricultural production in Southeast South America, although extremely long dry spells have become more frequent affecting the economies of large cities in southeast Brazil. Inversely, reduced precipitation and altered rainfall at the start and end of the rainy season and during the mid-summer drought is impacting rainfed subsistence farming particularly in the Dry Corridor in Central America and in the tropical Andes compromising food security (*high confidence*). The crop growth duration for maize for those regions was reduced by at least 5% between 1981-2010 and 2015-2019. {12.3.1, 12.3.2, 12.3.6, Table 12.4}

Climate change affects the epidemiology of climate-sensitive infectious diseases in the region (*high confidence*). Examples are the effects of warming temperatures on increasing the suitability of transmission of vector-borne diseases, including endemic and emerging arboviral diseases such as dengue fever, chikungunya, and Zika (*medium confidence*). The reproduction potential for the transmission of dengue increased between 17% and 80% for the period 1950-54 to 2016-2021 depending on the subregion as a result of changes in temperature and precipitation (*high confidence*). {12.3.1, 12.3.2, 12.3.3, 12.3.5, 12.3.6, Table 12.1}

The Andes, northeast Brazil and the northern countries in Central America are among the more sensitive regions to climatic-related migrations and displacements, a phenomenon that has increased since AR5 (*high confidence*). Climatic drivers interact with social, political, geopolitical and economical drivers; the most common climatic drivers for migration and displacements are droughts, tropical storms and hurricanes, heavy rains and floods (*high confidence*). {12.3.1.4, 12.3.2.4, 12.3.3.4, 12.3.5.4, 12.5.8.4}

The impacts of climate change are not of equal scope for men and women (*high confidence*). Women, particularly the poorest, are more vulnerable and are impacted in greater proportion. Often they have less capacity to adapt, further widening structural gender gaps (*high confidence*). {12.3.7.3, 12.5.2.4, 12.5.2.5, 12.5.7.3, 12.5.8.1, 12.5.8.3, 12.5.8.4}

Current adaptation responses:

Ecosystem-based adaptation is the most common adaptation strategy for terrestrial and freshwater ecosystems (*high confidence*). There is a focus on the protection of native terrestrial vegetation through implementation of protected areas and payment for ecosystem services, especially those related to water provision. The adaptation measures in place, however, are insufficient to safeguard terrestrial and freshwater ecosystems in the CSA from negative impacts of climate change (*high confidence*). {12.5.1, 12.5.3, 12.6}

Adaptation initiatives in ocean and coastal ecosystems mainly focus on conservation, protection and restoration) (*high confidence*). The main adaptation measures are ocean zoning, the prohibition of productive activities (e.g., fisheries, aquaculture, mining, tourism) on marine ecosystems, the improvement of research and education programs, and the creation of specific national policies (*high confidence*). {12.5.2}

Adaptive water management has mainly centred on enhancing quantity and quality of water supply, including large infrastructure projects, which, however, are often contested and can exacerbate water related conflicts (*high confidence*). Inclusive water regimes that overcome social inequalities and approaches including nature-based solutions, such as wetland restoration and water storage and infiltration infrastructure, with synergies for ecosystem conservation and disaster risk reduction, have been found to be more successful for adaptation and sustainable development (*high confidence*). {12.5.3, 12.6.1, 12.6.3}

Adaptation strategies for agricultural production are increasing in the region as a response to current and projected changes in climate (*high confidence*). The main observed adaptation strategies in agriculture and forestry are soil and water management conservation, crop diversification, climate-smart agriculture, early warning systems, upward shifting for plantations to avoid warming habitat and pests and improved management of pastures and livestock. Adaptation requires governance improvements and new strategies to address changing climate; nevertheless, barriers limiting adaptive capacity persist such as lack of educational programs for farmers, adequate knowledge of site-specific adaptation and institutional and financial constraints (*high confidence*). {12.5.4}

Urban adaptation in the region includes solutions on regulation, planning, urban waters management and housing (*high confidence*). Regulation, planning and control systems are central tools on reducing risk associated with the security of the buildings, their location, and the proper supply of basic urban services and transport (*high confidence*). The adoption of nature-based solutions (e.g., urban agriculture and rivers restoration) and hybrid (grey-green) infrastructure are still incipient with weak connections to poverty and inequality reduction strategies (*medium confidence*). Focusing on risk reduction encompasses upgrading informal and precarious settlements, built-environments, and improving housing conditions, which offer an important but still limited contribution to urban adaptation (*high confidence*). {12.5.5, 12.5.7, 12.6.1}

Adaptation initiatives for the health sector are mainly focused on the development of climate services such as integrated climate-health surveillance and observatories, forecasting climate-related disasters and vulnerability maps (*high confidence*). Climate services for the health sector are largely focused on epidemic forecast tools and associated early warning systems for vector-borne diseases and heat and cold waves. Political, institutional and financial barriers reduce the feasibility of implementing these tools (*high confidence*). {12.5.6, Table 12.9, Table 12.11}

Indigenous knowledge and local knowledge are crucial for the adaptation and resilience of social-ecological systems (*high confidence*). Indigenous knowledge and local knowledge can contribute to reducing the vulnerability of local communities to climate change (*medium confidence*). {12.5.1, 12.5.8, 12.6.2}

What are the projected impacts and key risks?

Climate change is projected to convert existing risks in the region into severe key risks (*medium confidence*). Key risks are assessed as follows: 1. Risk of food insecurity due to droughts; 2. Risk to people and infrastructure due to floods and landslides; 3. Risk of water insecurity due to declining snow cover, shrinking glaciers and rainfall variability; 4. Risk of increasing epidemics particularly of vector-borne diseases; 5. Cascading risks surpassing public service systems; 6. Risk of large-scale changes and biome shifts in the Amazon; 7. Risks to coral reef ecosystems; and 8. Risks to coastal socio-ecological systems due to sea level rise, storm surges and coastal erosion. {12.3, 12.4, Figure 12.9, Figure 12.11, Table 12.6, Table SM12.5}

Impacts on rural livelihoods and food security, particularly for small and medium-sized farmers and Indigenous Peoples in the mountains, are projected to worsen, including the overall reduction of agricultural production, suitable farming area and water availability (*high confidence*). Projected yield reductions by 2050 under A2 scenario are: bean 19%, maize 4–21%, rice 23% in Central America with seasonal droughts projected to lengthen, intensify and increase in frequency. Small fisheries and farming of seafood will be negatively affected as ENSO events become more frequent and intense and ocean warming and acidification continues (*medium confidence*). {12.2, 12.3, 12.4, Figure 12.9, Figure 12.11, Table 12.4}

Extreme precipitation events, which result in floods, landslides and droughts, are projected to intensify in magnitude and frequency due to climate change (*medium confidence*). Floods and landslides pose a risk to life and infrastructure; a 1.5ºC increase would result in an increase of 100–200% in the population affected by floods in Colombia, Brazil and Argentina, 300% in Ecuador and 400% in Peru (*medium confidence*). {12.3, Figure 12.7, Figure 12.9, Table SM12.5}

Increasing water scarcity and competition over water are projected (*high confidence*). Disruption in water flows will significantly degrade ecosystems such as high-elevation wetlands and affect farming communities, public health and energy production (*high confidence*). {12.3, Figure 12.3, Figure 12.9, Figure 12.11}

In the next decades, endemic and emerging climate-sensitive infectious diseases are projected to increase (*medium confidence*). This can happen through expanded distribution of vectors, especially viral infectious diseases from zoonotic origin in transition areas between urban and suburban, or rural settings, and upslope in the mountains (*medium confidence*). {12.3.2, 12.3.5, 12.3.7, Figure 12.5, Figure 12.9, Figure 12.11, Table 12.6, Table SM12.5}

The positive feedback between climate change and land use change, particularly deforestation, is projected to increase the threat to the Amazon forest, resulting in the increase of fire occurrence, forest degradation (*high confidence*) and long-term loss of forest structure (*medium confidence*). The combined effect of both impacts will lead to a long-term decrease in carbon stocks in forest biomass, compromising Amazonia´s role as a carbon sink, largely conditional on the forest's responses to elevated atmospheric CO_2 (*medium confidence*). The southern portion of the Amazon has become a net carbon source to the atmosphere in the past decade (*high confidence*). {12.3.3, 12.3.4, Figure 12.9, Figure 12.11, Table 12.6, Table SM12.5}

Up to 85% of natural systems (plant and animal species, habitats and communities) evaluated in the literature for biodiversity-rich spots in the region are projected to be negatively impacted by climate change (*medium confidence*). Available studies focus mainly on vertebrates and plants of the Atlantic Forest and Cerrado in Brazil and in Central America, with a large knowledge gap on freshwater ecosystems {12.3, 12.5.1, CCP1}

Ocean and coastal ecosystems in the region will continue to be highly impacted by climate change (*high confidence*). Coral reefs are projected to lose their habitat, change their distribution range and suffer more bleaching events driven by ocean warming. In the RCP4.5 and RCP8.5 scenarios by 2050, virtually every coral reef will experience at least one severe bleaching event per year (*high confidence*). Under all RCP scenarios of climate change, there will be changes in the geographical distribution of marine species and ocean and coastal ecosystems such as mangroves, estuaries, rocky shores, as well as those species subjected to fisheries (*medium confidence*). {Figure 12.9, Table SM12.3, Table SM12.4}

Contribution of adaptation to solutions and barriers to adaptation

Policies and actions at multiple scales and the participation of actors from all social groups, including the most exposed and vulnerable populations, are critical elements for effective adaptation (*high confidence*). Engaging social movements and local actors in policy-making and planning for adaptation generates positive synergies and better results. Adaptation policies and programs that consider age, socioeconomic status, race, and ethnicity are more efficient, as these factors determine vulnerability and potential benefits of adaptation. Socio-economic and political factors that provide some level of safety and continuity of policies and actions are critical enablers of adaptation (*high confidence*). {12.5.1, 12.5.2, 12.5.7, 12.5.8, 12.6.4}

The knowledge and awareness of climate change as a threat has been increasing since AR5 due to the increasing frequency and magnitude of extreme weather events in the region, information available and climate justice activism (*high confidence*). Conflicts in which direct biophysical impacts of climate change play a major role can unleash protests and strengthen social movements (*medium confidence*). {12.5.8, 12.6.4}

Research approaches that integrate Indigenous knowledge and local knowledge systems, with natural and social sciences, have increased since AR5 (*high confidence*), and are helping to improve decision-making processes in the region, reduce maladaptation, and foster transformational adaptation through the integration with ecosystem-based adaptation and community-based adaptation (*high confidence*). {12.5.1, 12.5.8, 12.6.2}

The most reported obstacle for adaptation in terrestrial, freshwater, ocean and coastal ecosystems is financing (*high confidence*). There is also a significant gap in identifying limits to adaptation and weak institutional capacity for implementation. This hinders the development of comprehensive adaptation programs, even under adequate funding. {12.5.1, 12.5.2}

Climate Smart Agriculture technologies strengthening synergies among productivity and mitigation is growing as an important adaptation strategy in the region (*high confidence*). Pertinent information for farmers provided by Climate Information Services are helping them to understand the role of climate *vs.* other drivers in perceived productivity changes. Index insurance builds resilience and contributes to adaptation both by protecting farmers' assets in the face of major climate shocks, by promoting access to credit, and by the adoption of improved farm technologies and practices. {12.5.4}

Institutional instability, fragmented services and poor water management, inadequate governance structures, insufficient data and analysis of adaptation experience are barriers to address the water challenges in the region (*high confidence*). {12.5.3}

Inequality, poverty and informality shaping cities in the region increase vulnerability to climate change while policies, plans or interventions addressing these social challenges with inclusive approaches are opportunities for adaptation (*high confidence*). Initiatives to improve informal and precarious settlement, guaranteeing access to land and decent housing, are aligned with comprehensive adaptation policies that include development and reduction of poverty, inequality and disaster risk (*medium confidence*). {12.5.5, 12.5.7}

Adaptation policies often address climate impact drivers, but seldom include the social and economic underpinnings of vulnerability. This narrow scope limits adaptation results and compromises their continuity in the region (*high confidence*). In a context of unaddressed underdevelopment, adaptation policies tackling poverty and inequality are marginal, underfunded, and not clearly included at national, regional or urban levels. Dialogue and agreement including multiple actors are mechanisms to acknowledge trade-offs and promote dynamic, site-specific adaptation options (*medium confidence*). {12.5.7}

12.1 Introduction

12.1.1 The Central and South America Region

Central and South America (CSA) is a highly diverse region, both culturally and biologically. It harbours one of the highest biodiversity on the planet (Hoorn et al., 2010; Zador et al., 2015; IPBES, 2018a) (Cross-Chapter Paper 1: Biodiversity Hotspots) and a wealth of cultural diversity resulting from more than 800 Indigenous Peoples who share the territory with European and African descendants and more recent Asian migrants (CEPAL, 2014). Moreover, it is one of the most urbanized regions in the world, with some of the most populated metropolitan areas (UNDESA, 2019). Several countries in the region have experienced sustained economic growth in the last decades, making important advances in reducing poverty in the area. Yet, it is a region of substantial social inequality including the highest inequality in land tenure, where there still remains a large percentage of the population below the poverty line, unequally distributed between rural and urban areas and along aspects like gender and race; these groups are highly vulnerable to climate change and natural extreme events that frequently affect the region (*high confidence*) (ECLAC, 2019b; Busso and Messina, 2020; Poveda et al., 2020).

Land use changes in the region, particularly deforestation, are large, mostly due to agricultural production for export purposes, one of the main sources of income for the area (Salazar et al., 2016) (Figure 12.2c). Additional pressure on the land comes from illegal activities, pollution and induced fires. These changes exacerbate the impacts of climate change and make the region play a key role in the future of the world economy and food production (IPBES, 2018a). The region boasts the largest tropical forest on the planet and other important biomes of high biodiversity on mountains, lowlands and coastal areas. It can potentially continue its agricultural expansion and development at the expense of substantially reducing the areas of natural biomes. Indigenous Peoples and smallholder families are lacking adequate climate policies combined with institutions to protect their property rights; this could result in a more sustainable process of agricultural expansion, without substantially increasing greenhouse gas emissions and the vulnerability of those populations (*high confidence*) (Sá et al., 2017).

Central and South America (CSA) is divided into eight climatic sub-regions by WGI (Figure 12.1). Though the southern part of Mexico is included in the climatic sub-region SCA for WGI, Mexico is assessed in Chapter 14 (North America). In this chapter, we refer to this sub-region as Central America (CA) as it excludes southern Mexico. The climate change literature for the region occasionally includes Mexico and in those cases, our assessment makes reference to Latin America but when only southern Mexico is included, the term Mesoamerica is used. Figure 12.2 and Table SM12.1 summarize relevant characteristics of the sub-regions included in this chapter.

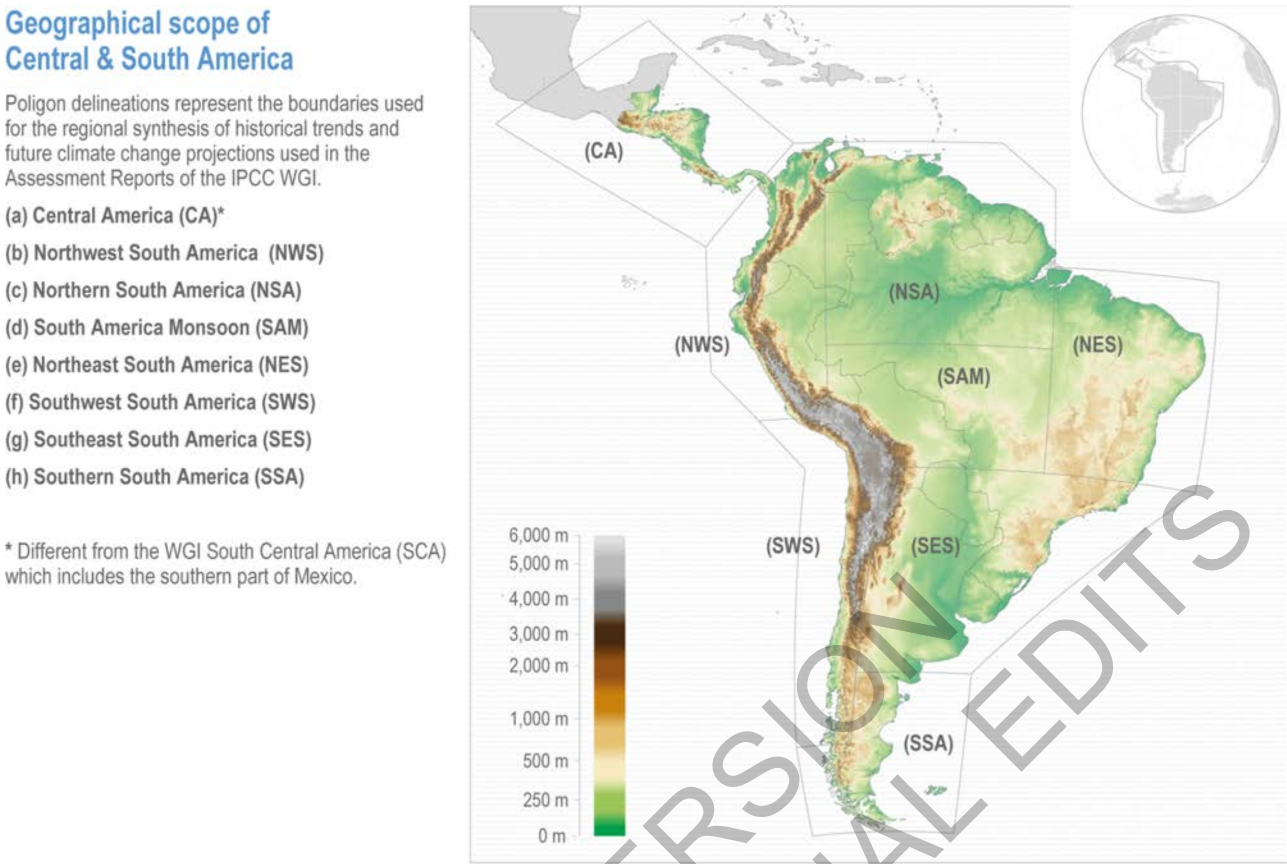

Figure 12.1: Sub-regions included in the Central and South America region. Note that the WGI climatic sub-region South Central America SCA corresponds to Central America CA in this chapter, as southern Mexico is included in Chapter 14. Small islands in the region are approached in Chapter 15 in more detail.

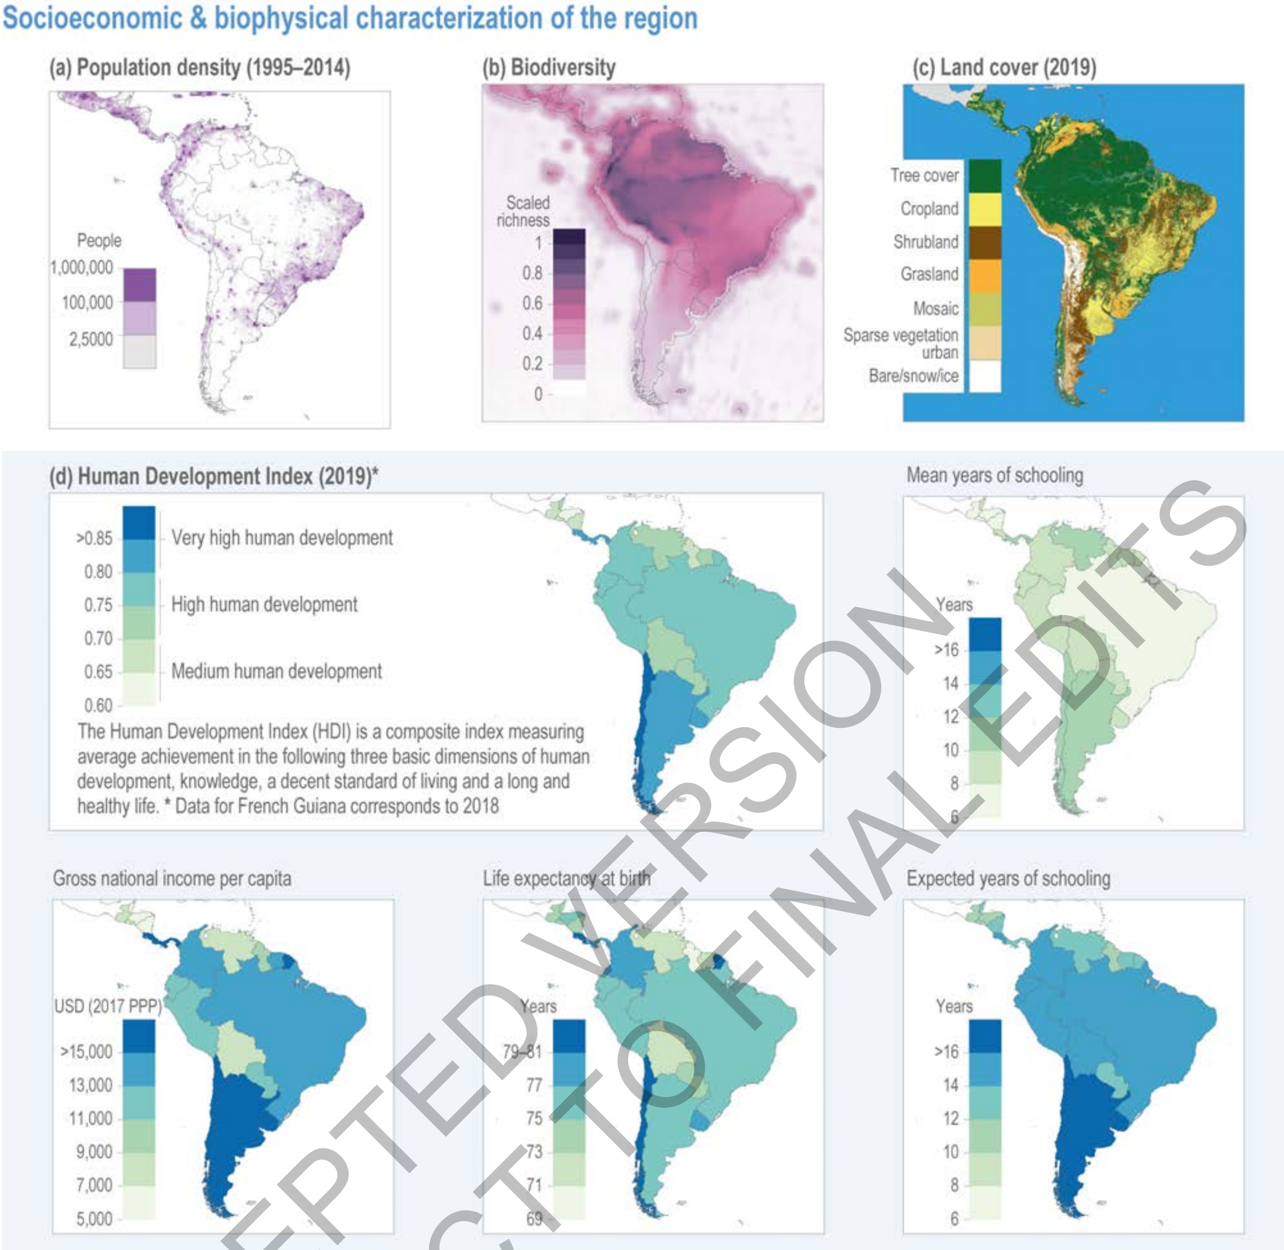

Figure 12.2: Characterization of the region. Population data from ISIMIP (2021) after Klein Goldewijk et al. (2017). Biodiversity expressed as marine and terrestrial species richness adapted from Gagné et al. (2020). Land cover data from ESA (2018). Human Development Index and its components from UNDP (2020). HDI and components for French Guiana from Global Data Lab (2020).

12.1.2 Approach and Storyline for the Chapter

The chapter is divided in two main sections. The first section follows an integrative approach in which hazards, exposure, vulnerability, impacts and risks are discussed following the eight climatically homogeneous sub-regions described in WGI AR6 (see Figure 12.1). The second section assesses the implemented and proposed adaptation practices by sector; in doing so, it connects to the WGII AR6 cross-chapters themes. The storyline is then a description of the hazards, exposure, vulnerability and impacts providing as much detail as available in the literature at the sub-regional level, followed by the identification of risks as a result of the interaction of those aspects. This integrated sub-regional approach ensures a balance in the text, particularly for countries that are usually underrepresented in the literature but that show a high level of vulnerability and impacts, such as those observed in CA. The sectoral assessment of adaptation that follows is useful for policy makers and implementers, usually focused and organized by sectors, governments' ministries or secretaries that can easily locate the relevant adaptation information for their particular sector. To ensure coherence in the chapter, a summary of the assessed adaptation options by key risks is presented, followed by a feasibility assessment for some relevant adaptation options. The chapter closes with case studies and a discussion of the knowledge gaps evidenced in the process of the assessment.

12.2 Summary of the Fifth Assessment Report and Recent IPCC Special Reports

Central and South America shows increasing trends of climatic change and variability and extreme events severely impacting the region, exacerbating problems of rampant and persistent poverty, precarious health systems and water and sanitation services, malnutrition and pollution. Inadequate governance and lack of participation escalates the vulnerability and risk to climate variability and change in the region (*high confidence*) (WGII AR5 Chapter 27) (Magrin et al., 2014).

Increasing trends in precipitation had been observed in Southeast South America (SES in Figure 12.1) in contrast with decreasing trends in CA and central-southern Chile (*high confidence*) (WGII AR5 Chapter 27) (Magrin et al., 2014). Frequency and intensity of droughts have increased in many parts of SA (IPCC, 2019c). Warming has been detected throughout CSA except for a cooling trend reported for the ocean off the Chilean coast.

Climate projections indicate increases in temperature for the entire region by 2100 for RCP4.5 and RCP8.5, but rainfall changes will vary geographically, with a notable reduction of –22% in Northeast Brazil and an increase of +25% in SES. Significant dependency on rainfed agriculture (>30% in Guatemala, Honduras, and Nicaragua) indicates high sensitivity to climatic variability and change, and challenge food security (*high confidence*) (SRCCL Chapter 5, Mbow et al., 2019). Undernutrition has worsened since 2014 in CSA (SRCCL Chapter 5, Mbow et al., 2019). Evidence of climate change impacts on food security is emerging from Indigenous knowledge and local knowledge studies in SA. Municipalities in CA with high proportion of subsistence crops tend to have less resources for adaptation and more vulnerable to climate change (SRCCL Chapter 5, Mbow et al., 2019). Rising temperature and decreased rainfall could reduce agricultural productivity by 2030, threatening food security of the poorest populations (WGII AR5 Chapter 27, Magrin et al., 2014). Though reduced suitability and yield for beans, coffee, maize, plantain, and rice is expected in CA (SRCCL Chapter 5, Mbow et al., 2019), limiting the warming to 1.5ºC, compared with 2ºC, is projected to result in smaller net reductions in yields of maize, rice, wheat and other cereal crops for CSA (*high confidence*) (SR15 Chapter 3, Hoegh-Guldberg et al., 2018). The heat stress is expected to reduce the suitability of Arabica coffee in Mesoamerica but it can improve in high latitude areas in SA (SRCCL Chapter 4, Olsson et al., 2019). There is *limited evidence* that these declines in crop yields may result in significant population displacement from the tropics to the subtropics (SR15 Chapter 3, Hoegh-Guldberg et al., 2018).

There is a *high confidence* that heat waves will increase in frequency, intensity and duration, becoming, under high emission scenarios, extremely long, over 60 days in duration in SA; the risk of wildfires will also increase significantly in SA (SRCCL Chapter 2, Jia et al., 2019). These processes are and will lead to increased desertification that cost between 8 and 14% of gross agricultural product in many CSA countries (SRCCL Chapter 3, Mirzabaev et al., 2019). Distinguishing climate induced changes from land use changes is challenging, but 5–6% of biomes in SA are expected to change by 2100 due to climate change (SRCCL Chapter 4, Olsson et al., 2019).

Changes in weather and climatic patterns are negatively affecting human health in CSA, in part through the emergence of diseases in previously non-endemic areas (WGII AR5 Chapter 27, Magrin et al., 2014). Projections of potential impacts of climate change on malaria confirm that weather and climate are among the drivers of geographic range, intensity of transmission, and seasonality; the changes of risk become more complex with additional warming (*very high confidence*) (SR15 Chapter 3, Hoegh-Guldberg et al., 2018). There is *high confidence* that constraining the warming to 1.5°C would reduce risks for unique and threatened ecosystems safeguarding the services they provide for livelihoods and sustainable development (food, water) in CA and Amazon (SR15 Chapter 5, Roy et al., 2018).

Observed changes in streamflow and water availability affect vulnerable regions (WGII AR5 Chapter 27, Magrin et al., 2014). Glacier mass changes in the Andes over the past decades are among the most negative ones worldwide (SROCC Chapter 2, Hock et al., 2019). This reduction has modified the frequency, magnitude and location of related natural hazards, while the exposure of people and infrastructure has increased because in relation with growing population, tourism and economic development (*high confidence*) (SROCC Chapter 2, Hock et al., 2019).

Negative impacts of climate change in the region are exacerbated by deforestation and land degradation attributed mainly to expansion and intensification of agriculture and cattle ranching, usually under insecure-tenure land. This conversion of natural ecosystems is the main cause of biodiversity and ecosystem loss and is an important source of greenhouse gas (GHG) emissions (*high confidence*) (WGII AR5 Chapter 27, Magrin et al., 2014).

The combination of continued anthropogenic disturbance, particularly deforestation, with global warming may result in dieback of forest in the region (*medium confidence*) (SR15 Chapter 3, Hoegh-Guldberg et al., 2018). Loses as high as 40% of biomass are projected in CA with a warming of 3°C–4°C and the Amazon may experience a significant dieback at similar warming levels (SR15 Chapter 3, Hoegh-Guldberg et al., 2018). Advances in second-generation bioethanol from sugarcane and other feedstock will be important for mitigation. However, agricultural expansion results in large conversions in tropical dry woodlands and savannas in SA (Brazilian Cerrado, Caatinga and Chaco) (*high confidence*) (SRCCL Chapter 1, Arneth et al., 2019). The expansion of soybean plantations in the Amazonian state of Mato Grosso in Brazil reached 16.8% yr^{-1} from 2000 to 2005; and oil palm, a significant biofuel crop, is also linked to recent deforestation in tropical CA (Costa Rica and Honduras) and SA (Colombia and Ecuador), although lower in magnitude compared to deforestation from soybean and cattle ranching (WGII AR5 Chapter 27, Magrin et al., 2014).

Ocean and coastal ecosystems in the region already show important changes due to climate change and global warming (SROCC Chapter 5, Bindoff et al., 2019).

Adaptation to future climate changes starts by reducing the vulnerability to present climate considering the deficient welfare of people in the region. Generalizing to the region cases of synergies among development, adaptation and mitigation planning requires a governance model where development needs, vulnerability reduction, and adaptation strategies are intertwined (WGII AR5 Chapter 27, Magrin et al., 2014).

12.3 Hazards, Exposure, Vulnerabilities and Impacts

12.3.1 Central America (CA) Sub-region

12.3.1.1 Hazards

Since the mid-20th century, extreme warm temperatures have increased and extreme cold temperatures have decreased in the region (*medium confidence*). The magnitude and frequency of extreme precipitation events have increased, but droughts have mixed signals (*low confidence*) (WGI AR6 Table 11.13, Table 11.14, Table 11.15, Seneviratne et al., 2021). There are spatially variable trends detected for the mid-summer drought (MSD) timing, the amount of rainy season precipitation, the number of consecutive and total dry days, and extreme wet events at the local scale since the 1980s. At the regional scale, a positive trend in the duration, but not the magnitude of the MSD was found (Anderson et al., 2019).

Significant increases in tropical cyclone (TC) intensification rates in the Atlantic basin, highly unusual compared to model-based estimates of internal climate variations has been observed (Bhatia et al., 2019). TC contributed approximately 10% of the annual precipitation (Khouakhi et al., 2017). During the TC season more TC-driven events of extreme sea level exceed a 10-year return period (Muis et al., 2019).

Massive heat wave events and increase in the frequency of warm extremes are projected at the end of the 21st century (*high confidence*). When comparing 2.0 with 1.5 degrees of warming, the longest annual warm wave is projected to increase more than 60 days (Taylor et al., 2018).

General decrease in the magnitude of heavy precipitation extremes (Chou et al., 2014; Giorgi et al., 2014) (in 1.5ºC projection) but increase in the frequency of extreme precipitation (R50mm) (Imbach et al., 2018) are projected for both 2ºC and 4ºC GWL. Strong declines in mean daily rainfall are projected for July in Belize

(Stennett-Brown et al., 2017; WGI AR6 Table 11.14, Seneviratne et al., 2021) and decreased rainfall through the year for all capital cities except Panama City (*medium confidence: limited evidence, high agreement*) (Pinzón et al., 2017).

The main climate impact drivers like extreme heat, drought, relative sea level rise, coastal flooding, erosion, marine heatwaves, ocean aridity, (*high confidence*) and aridity, drought and wildfires will increase by mid-century (*medium confidence*) (Figure 12.6, WGI AR6 Table 12.6, Ranasinghe et al., 2021).

The rainy season in CA will likely experience more pronounced MSD by the end of this century, with a signal for reduced minimum precipitation by the mid-century for the JJA and SON quarters, and a broader second peak is projected consistent with the future south displacement of the ITCZ (*high confidence*) (Fuentes-Franco et al., 2015; Hidalgo et al., 2017; Maurer et al., 2017; Imbach et al., 2018; Naumann et al., 2018; Ribalaygua et al., 2018; Corrales-Suastegui et al., 2020).

Climate projections indicate a decrease in frequency of tropical cyclones in CA accompanied with an increased frequency of intense cyclones (WGI AR6 Section 12.4.4.3, Ranasinghe et al., 2021).

12.3.1.2 Exposure

Of the 47 million Central Americans in 2015, 40% lived in rural areas with Belize being the least urbanized (54% rural) and Costa Rica the most (21% rural) (CELADE, 2019); 10.5 million lived in the Dry Corridor region, an area recently exposed to severe droughts that have resulted in 3.5 million people in need of humanitarian assistance (FAO, 2016a). Except in Belize and Panama, the majority of the countries' population —ranging from 56% in Honduras to 95% in El Salvador— is exposed to 2 or more risks derived from natural extreme events, affecting between 57% to 96% of the GDP of the countries (UNISDR and CEPREDENAC, 2014). Central America is one of the regions most exposed to climatic phenomena; with long coastlines and lowland areas, the region is repeatedly affected by drought, intense rains, cyclones and ENSO events (*high confidence*) (ECLAC et al., 2015).

Large urban centres are located on mountains or away from the shore, with the notable exceptions of Panama City, Belmopan and Managua, capital cities housing around 3 million people. Urban development in the capital cities and suburbs has almost tripled in the last forty years reaching population densities as high as 11,000 inhabitants per km^2 in Guatemala City and Tegucigalpa, with the spread of poor neighbourhoods in steep ravines and other marginal high risk areas (Programa Estado de la Nación - Estado de la Región, 2016).

12.3.1.3 Vulnerability

Climate change is exacerbating socioeconomic vulnerability in CA, a region with high levels of socioeconomic, ethnic and gender inequality, high rates of child and maternal mortality and morbidity, high levels of malnutrition and inadequate access to food and drinking water (ECLAC et al., 2015). Disasters from adverse natural events exacerbate CA's economic vulnerability, accounting for substantial human and economic losses (UNISDR and CEPREDENAC, 2014). Vulnerability in most sectors is considered high or very high (*high confidence*) (Figure 12.7).

Approximately 40% of the CA population are living in poverty. Guatemala (62%), Honduras (60%), Nicaragua (46%) and Belize (42%, 2009) had the highest poverty rates in CSA in 2018 (ECLAC, 2019b; BCIE, 2020). Rural poverty rates are higher, 82% in Honduras and 77% in Guatemala in 2014, and so is poverty among Indigenous Peoples, up to 79% in Guatemala. Rural poor are the most sensitive to climate extremes as their main economic activity is based on agriculture in vulnerable terrains (NU CEPAL, 2018). In 2014, all CA countries, except for El Salvador (excluding Belize), had higher GINI coefficients (more inequality) than the average for Latin America (0.473), which in itself is the most unequal region in the world (ECLAC, 2019b); in 2018 the situation remained similar with El Salvador showing the lowest GINI coefficient (40) and the rest of the countries showing values higher than the Latin-American average (BCIE, 2020).

12.3.1.4 Impacts

The countries in the region are consistently ranked with the highest risk in the world of being impacted by extreme events (*high confidence*). Economic cost of climate change impacts in 2010 was estimated from 2.9% of GDP for Guatemala to 7.7% for Belize (ECLAC et al., 2015). For the period 1992–2011, Honduras, Nicaragua and Guatemala were among the 10 most impacted countries in the world by extreme weather events (UNISDR and CEPREDENAC, 2014). The number of these events has increased 3% annually in the last 30 years (Bárcena et al., 2020a).

Human and economic losses, changing water availability and increasing food insecurity are the most studied impacts of climate change in CA (Figure 12.9; Harvey et al., 2018; Hoegh-Guldberg et al., 2019). Hydro-meteorological events, such as storm surges and tropical cyclones, are the most frequent extreme events and have the highest impact (*high confidence*) (Reyer et al., 2017). From 2005 to 2014, the cumulative impacts were over 3410 people dead, hundreds of thousands displaced, and damages estimated around USD 5.8 billion (Ishizawa and Miranda, 2016). One standard deviation in the intensity of a hurricane windstorm leads to a decrease in both the growth of total GDP per capita (0.9% to 1.6%) and total income and labour income by 3%, whereas it increases moderate and extreme poverty by 1.5% in CA (Ishizawa and Miranda, 2016).

Food insecurity is a serious impact of climate change in a region where 10% of the GDP depends on agriculture, livestock and fisheries (*very high confidence*) (ECLAC et al., 2015; CEPAL et al., 2018; Harvey et al., 2018; BCIE, 2020). Crop losses largely result from highly variable rainfall and seasonal droughts which have increased significantly in the last decades (Table 12.3; CEPAL and CAC-SICA, 2020), particularly the observed changes in the MSD that reduces rainfall at the onset of the rainy season (May-June) (Anderson et al., 2019). Small and subsistence farmers receive the highest impact as they practice rainfed agriculture (Imbach et al., 2017), and poor neighbourhoods, which face socioeconomic and physical barriers for adapting to climate change (Kongsager, 2017). In 2015, precipitation diminished between 50% to 70% of its historic average causing the loss of up to 80% of beans and 60% of maize, leaving 2.5 million people food insecure, 1.6 million of which were in the Dry Corridor of CA (ECLAC et al., 2015; FAO, 2016a). In 2019, the region entered its fifth consecutive drought year with 1.4 million people in need of food aid. Seasonal-scale droughts are projected to lengthen by 12–30%, intensify by 17–42% and increase in frequency by 21–42% in RCP4.5 and RCP8.5 scenarios by the end of the century (Depsky and Pons, 2021).

Studies have shown that the incidence of some vector-borne and zoonotic diseases in CA is correlated to climatic variables, particularly temperature and rainfall (*high confidence*) (Figure 12.4; Table 12.1). In Honduras, rainfall and relative humidity were positively correlated with the occurrence of hemorrhagic dengue cases (Zambrano et al., 2012). In Costa Rica, temperature and rainfall was correlated to cattle rabies outbreaks and mortality during 1985–2016 (Hutter et al., 2018); Incidence of leishmaniasis showed cycles of three years related to temperature changes (Chaves and Pascual, 2006); and snakebites were more likely to occur at high temperatures and was significantly reduced after the rainy season for the period 2005–2013 (Chaves et al., 2015). In Panama, rainfall was associated with the increased number of malaria cases among the Gunas, an Indigenous People with high vulnerability living in poverty conditions on small islands affected by sea-level rise (Hurtado et al., 2018). These correlations point to a possible change in disease incidence with climate change; evidence of that change is yet to be reported in the literature as longitudinal studies are lacking in the region.

Heat stress is another health concern in this already warm and humid part of the world (*high confidence*) (Table 12.2); it is an increasing occupational health hazard with potential impacts on kidney disease (Sheffield et al., 2013; Dally et al., 2018; Johnson et al., 2019). Sea-level rise exacerbating wave-driven flooding is expected to impact infrastructure and freshwater availability in small islands and atolls off the coast of Belize (Storlazzi et al., 2018). Observed and expected impacts in the coastal and ocean ecosystems of the sub-region are described in Figure 12.9.

Decreasing water availability is another impact of climate change (*high confidence*). Under a climate change scenario of 3.5°C warming and a 30% reduction of rainfall, a reduction in production and export of crops and livestock is projected affecting the wages and decreasing the GDP of Guatemala by 1.2%, thereby increasing food insecurity (Vargas et al., 2018b). By 2100, water availability per capita is projected to decrease 82% and 90% on average for the region under B2 (low emissions) and A2 (high emissions) scenarios respectively (CEPAL, 2010) (Figure 12.3).

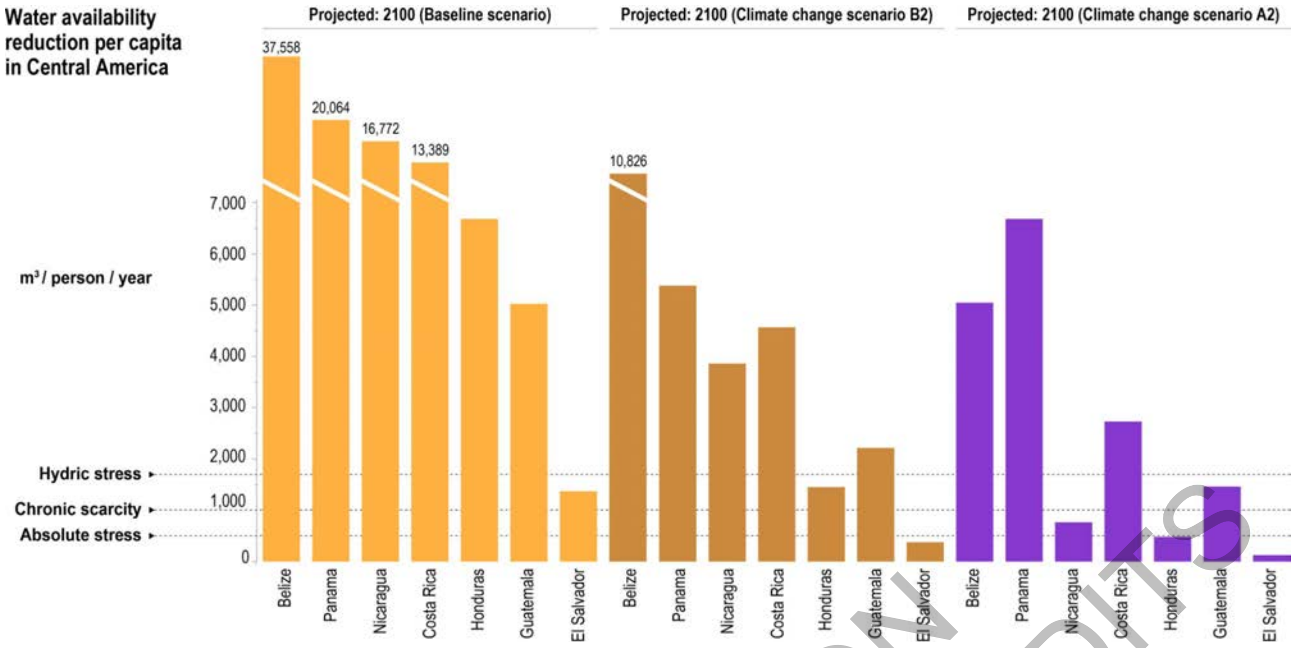

Figure 12.3: Reduction of water availability per capita projected to 2100 without climate change (baseline scenario) and with two climate change scenarios (CEPAL, 2010).

Impacts on rural livelihoods, particularly for small and medium-sized farmers and Indigenous Peoples on the mountains, include the overall reduction of the production, yield (Table 12.4), suitable farming area, and water availability (*high confidence*) (Walshe and Argumedo, 2016; Bouroncle et al., 2017; Hannah et al., 2017; Imbach et al., 2017; Harvey et al., 2018; Batzín, 2019; Donatti et al., 2019). Bean production in El Salvador, Nicaragua, Honduras, and Guatemala, is projected to decrease, using the Decision Support for Agro-Technology Transfer (DSSAT) under A2 scenario, by 19% for 2050, whereas maize production, depending on water retention capacity of soils, will drop between 4% and 21% by 2050 (CEPAL et al., 2018). In Guatemala, the yield of rainfed maize is expected to decrease by 16% by 2050 under RCP8.5 using the Global Gridded Crop Model Intercomparison GGCMI; yields for rainfed sugarcane are expected to drop by 44% and irrigated sugarcane by 36% under the same modelling conditions (Castellanos et al., 2018). Rice production is expected to decrease by 23% under scenario A2 by 2050 (CEPAL and CAC/SICA, 2013).

The extent and quality of suitable areas for basic grains are expected to contract (*high confidence*). The suitable area for maize will experience a 35% reduction of cultivated area expected by 2100 under A2 scenario. The area suitable for beans is expected to reduce by 2050. Projections show that suitable areas with excellent aptitude under current conditions will decrease by 14%, mainly in Panama (41%) Costa Rica (21%) and El Salvador (20%). Species Distribution Model, using the IPSL GCM, projects that the suitable zones for cacao and coffee will shrink between 25% to 75% under RCP6.0 (Fernandez-Manjarrés, 2018; Fernández Kolb et al., 2019). Warmer and dryer lower areas will become unsuitable for coffee and will drive its production to higher land (Läderach et al., 2013; Bunn et al., 2015). Under A2 climate change scenario, areas with excellent aptitude for Arabica coffee will decrease by 12% in Central America; coffee yield will decrease in suitable zones whereby the extent of high yield (> 0.8 T ha^{-1}) zones is project to shrink from 34% to 12% whereas low yield (< 0.3 T ha^{-1}) zone will expand from 14% to 36% by 2100 under A2 scenario (CEPAL and CAC/SICA, 2014).

The Mesoamerica, biodiversity-rich spot spanning through CA and southern Mexico is a global priority for terrestrial biodiversity conservation, and it is projected to be negatively impacted by climate change, especially through the contraction of distribution of native species at the area becomes increasingly dryer (*high confidence*) (Cross-Chapter Paper 1.2.2; Feeley et al., 2013; Manes et al., 2021) . A significant reduction in net primary productivity in tropical forests is expected under both RCP4.5 and RCP8.5 as a result of temperature increase, precipitation reduction, and droughts (Lyra et al., 2017; Castro et al., 2018; Stan et al., 2020). Models of aridity index show that the dry, sub humid vegetation of the dry corridor will expand to neighbouring areas and replace the humid forests in the Pacific lowlands and the northern parts of Guatemala by 2050 under RCP4.5 and RCP8.5 scenarios (Pons et al., 2018; CEPAL and CAC-SICA, 2020).

3°C warming would shrink the tropical rainforest and replace it with savannah grassland. Wetlands are also expected to be highly affected by climate change in the region (Hoegh-Guldberg et al., 2019).

12.3.2 Northwest South America (NWS) Sub-region

12.3.2.1 Hazards

Significant increases in the intensity and frequency of hot extremes and significant decreases in the intensity and frequency of cold extremes (Dereczynski et al., 2020; Dunn et al., 2020) was *likely*[2] observed (Figure 12.6; WGI AR6 Table 11.13, Seneviratne et al., 2021).

Insufficient data coverage and trends in available data are generally not significant for heavy precipitation (*low confidence*) (Dereczynski et al., 2020; Dunn et al., 2020; Sun et al., 2021) (Figure 12.6; WGI AR6 Table 11.14) (Seneviratne et al., 2021).

ENSO is the dominant phenomenon affecting weather conditions in all CSA, and along the Pacific Coast of NWS with effects of heavy rains, storms, floods, landslides, heat and cold waves and extreme sea level rise (Ashok et al., 2007; Reguero et al., 2015; Wang et al., 2017b; Muis et al., 2018; Rodríguez-Morata et al., 2018; Rodríguez-Morata et al., 2019; Cai et al., 2020). There is a *medium confidence* that extreme ENSO will increase long after 1.5°C warming stabilization according to CMIP5 (Cai et al., 2015; Wang et al., 2017b; Cai et al., 2018). It is *very likely* that ENSO rainfall variability, used for defining extreme El Niño and La Niña, will increase significantly, regardless of amplitude changes in ENSO SST variability, by the second half of the 21st century in scenarios SSP2-4.5, SSP3-7.0, and SSP5-8.5 (WGI AR6 Chapter 4; Lee et al., 2021).

Warming and drier conditions are projected through the reduction of total annual precipitation, extreme precipitation and consecutive wet days, and increase in consecutive dry days (Chou et al., 2014). Heat waves will increase in frequency and severity in places close to the equator as Colombia (Guo et al., 2018; Feron et al., 2019), with decrease but strong wetting in coastal areas, pluvial and river flood, and mean wind increase (Mora et al., 2014). Models project for a 2ºC GWL *very likely* increase in the intensity and frequency of hot extremes and decrease in the intensity and frequency of cold extremes. Nevertheless, models project inconsistent changes in the region for extreme precipitation (*low confidence*) (Figure 12.6; WGI AR6 Table 12.14; Ranasinghe et al., 2021). The main climate impact drivers in the region, like extreme heat, mean precipitation and coastal and oceanic will increase and snow, ice and permafrost will decrease with *high confidence* (WGI AR6 Table 12.6, Ranasinghe et al., 2021).

12.3.2.2 Exposure

There is *high confidence* that coastal lowlands are exposed to sea level rise in the form of coastal flooding and erosion, subsidence and saltwater intrusion (Hoyos et al., 2013). Those hazards can affect settlements, ports, industries and other infrastructures. Mangrove and aquaculture areas are among the most exposed systems (Gorman, 2018). The Eastern Tropical Pacific, particularly Sector Niño 3.4, will see the worst increase in sea surface temperature, affecting industrial and small-scale fisheries (*very high confidence*) (Castrejón and Defeo, 2015; Reguero et al., 2015; Eddy et al., 2019; Bertrand et al., 2020; Castrejón and Charles, 2020; Escobar-Camacho et al., 2021).

Settlements and agriculture of different scales, and hydroelectric infrastructures, especially near big rivers or in plains, are exposed to floods. Exposure and vulnerabilities to precipitation, overflows and related landslides, are increasing (Briones-Estébanez and Ebecken, 2017).

[2] In this Report, the following terms have been used to indicate the assessed likelihood of an outcome or a result: Virtually certain 99–100% probability, Very likely 90–100%, Likely 66–100%, About as likely as not 33–66%, Unlikely 0–33%, Very unlikely 0–10%, and Exceptionally unlikely 0–1%. Additional terms (Extremely likely: 95–100%, More likely than not >50–100%, and Extremely unlikely 0–5%) may also be used when appropriate. Assessed likelihood is typeset in italics, e.g., *very likely*). This Report also uses the term '*likely* range' to indicate that the assessed likelihood of an outcome lies within the 17-83% probability range.

The Andean piedmont (500–1200 m.a.s.l.) ecosystems and crops and elevation ranges above the treeline are more exposed to thermal anomalies (*very high confidence*) (Urrutia and Vuille, 2009; Vuille et al., 2015; Aguilar-Lome et al., 2019; Pabón-Caicedo et al., 2020). Temperature rise, combined with precipitation and floods, leave people more exposed to epidemics (*very high confidence*) (Stewart-Ibarra and Lowe, 2013; Sippy et al., 2019; Petrova et al., 2020). A bigger exposure is related to lower socioeconomic conditions, poor health and marginalisation (Oliver-Smith, 2014).

12.3.2.3 Vulnerability

Local economies reliant on limited and specialized resources, highly dependent on ecosystem services such as water and soil fertility, as the alpaca and llama herders or small-scale fishers, are amongst the more vulnerable (*very high confidence*) (Hollowed et al., 2013; Postigo, 2013; Glynn et al., 2017; Duchicela et al., 2019). Also the agricultural sector in the face of extreme events (Coayla and Culqui, 2020). Their vulnerabilities increase as a result of unequal chains of value, incomplete transfers of technology and other socioeconomic and environmental drivers (*high confidence*) (Ariza-Montobbio and Cuvi, 2020; Gutierrez et al., 2020).

Informal housing and settlements, usually located in the highest risk land, exacerbates vulnerability (*very high confidence*) (Miranda Sara and Baud, 2014; Cuvi, 2015; Miranda Sara et al., 2016). The absence of proper drainage systems in urban areas increases the vulnerability, especially to floods. Most of the cities and infrastructure are considered highly vulnerable to climate change (*high confidence*) (Figure 12.7).

Regions dependent on glacier runoff are particularly vulnerable (Jiménez Cisneros et al., 2014; Mark et al., 2017; Polk et al., 2017). Also biodiversity and water dependent activities where seasonality and rainfall patterns are changing, and where other non-climatic sources of change, such as land use, affect the capacity of ecosystems to provide hydrological services (*very high confidence*) (Cerrón et al., 2019; Molina et al., 2020). The three countries are amongst the most vulnerable in terms of wellbeing and health Figure 12.7; Nagy et al., 2018).

12.3.2.4 Impacts

An increase in the frequency of climate related disasters has been reported (*high confidence*) (Huggel et al., 2015a; Stäubli et al., 2018) (WGI AR6 Chapter 12) (Ranasinghe et al., 2021). Scale studies indicate an increase of flood risk during the 21st century, consistent with more frequent floods, being worse in higher emission scenarios (*high confidence*) (Arnell and Gosling, 2013; Hirabayashi et al., 2013; Alfieri et al., 2017; WGI AR6 Chapter 12, Ranasinghe et al., 2021). Those living on riverbanks and slums built on steep slopes are among the most affected by floods of all kinds (*high confidence*) (Emmer et al., 2016; Emmer, 2017). There is still uncertainty in relation to future drought intensity and frequency (Pabón-Caicedo et al., 2020).

Increased sea surface temperature, coupled with stronger ENSO events, will affect marine life and fisheries by loss of productive habitat, disruption of nutrient structure, productivity, and altering the migration of species, leading to changes in fishing rates, impacting coastal livelihoods (*high confidence*) (Bayer et al., 2014; Cai et al., 2015; Ding et al., 2017; Mariano Gutiérrez et al., 2017; Bertrand et al., 2020). Figure 12.8 shows other observed sensitivities in several ecosystems and in places as the Galapagos and Malpelo islands, and the coastal Economic Exclusion Zone (EEZ).

ENSO events coupled with climate change, lead to warmer ocean temperatures, heavy rains, floods and heavy river discharges that have and will impact several activities, including small-scale fisheries infrastructure (*very high confidence*). In Peru alone, wet extremes are estimated to be at least 1.5 times more likely to happen compared to preindustrial times. The extremely wet ENSO event of 2017 left 6–9 billion USD in monetary losses in that country, 1.7 million inhabitants affected, and crops, roads, bridges, homes, schools, and health posts damaged or destroyed. Distinct types of ENSO events can have differentiated impacts (French and Mechler, 2017; Christidis et al., 2019; Takahashi and Martínez, 2019; Bertrand et al., 2020; Coayla and Culqui, 2020).

Irrigation, potable water, health and education infrastructures, as well as roads, bridges, cities, and housing buildings are frequently damaged or destroyed by extreme precipitations, having also impacts on sediment transport, river erosion and annual discharge (*very high confidence*) (Martínez et al., 2017; Morera et al., 2017; Isla, 2018; Rosales-Rueda, 2018; Salazar et al., 2018; Puente-Sotomayor et al., 2021). The increasing variability of precipitation has compromised rain-fed agriculture and power generation, particularly in the dry season (*high confidence*) (Bradley et al., 2006; Bury et al., 2013; Buytaert et al., 2017; Carey et al., 2017; Vuille et al., 2018; Orlove et al., 2019). For the Amazon-Andes transition zone, impacts of hydrological variability and transport of sediments have been noticed in riparian agriculture and biodiversity (*high confidence*) (Maeda et al., 2015; Espinoza et al., 2016; Vauchel et al., 2017; Ronchail et al., 2018; Ayes Rivera et al., 2019; Armijos et al., 2020; Figueroa et al., 2020; Pabón-Caicedo et al., 2020). Changes in seasonality and rain patterns are affecting coffee producers (Lambert and Eise, 2020).

Increases in vector-borne diseases can be related with the increase of rainfall and minimum temperatures during ENSO events (Stewart-Ibarra and Lowe, 2013) and the expansion of the diseases' altitudinal distribution (*high confidence*) (Lowe et al., 2017; Lippi et al., 2019; Portilla Cabrera and Selvaraj, 2020). ENSO events have been related with diseases such as dengue or leptospirosis (Quintero-Herrera et al., 2015; Sánchez et al., 2017; Arias-Monsalve and Builes-Jaramillo, 2019); they can also increase the incidence of Chikungunya (Section 7.2.2.1; Section 7.3.1.3). Precipitation, relative humidity and temperature have influenced dengue incidence over the last years (Mattar et al., 2013) (Table 12.1). Dengue cases are predicted to increase in the 1.5°C and the 3.7°C warming scenarios by 2050 and 2100, with increases ranging from 28,900 to 88,800 in Peru, 34,600 to 110,000 in Ecuador, and 97,400 to 317,000 in Colombia, although these scenarios do not consider the potential of vaccines or socioeconomic trajectories (Colón-González et al., 2018). Other studies found that *Aedes aegypti* (arbovirus vector) will shift into higher elevations, increasing the populations at risk (Lippi et al., 2019) (Figure 12.5). Climate change will contribute to increased malaria vectorial capacity (*high confidence*) (Laporta et al., 2015) (Section 7.2.2.1). Increases in minimum temperature were associated with historical malaria transmission when taking into consideration disease control interventions and climate factors (Fletcher et al., 2020). Figure 12.4 shows mixed changes in the number of months suitable for malaria transmission with low-lying areas in coastal regions becoming more suitable. Zoonotic tick-borne diseases and the epidemiology of tuberculosis are also influenced (Garcia-Solorzano et al., 2019; Rodriguez-Morales et al., 2019).

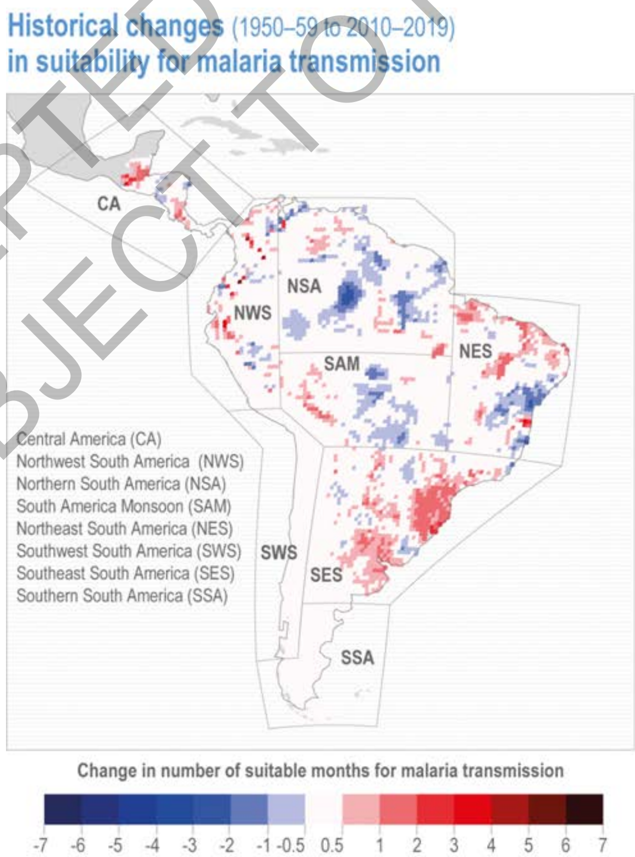

Figure 12.4: Change in the average number of months in a given year suitable for malaria transmission by *Plasmodium falciparum*, from 1950-1959 to 2010-2019. The threshold-based model used incorporates precipitation accumulation, average temperature, and relative humidity (Grover-Kopec et al., 2006; Romanello et al., 2021).

Accelerated warming is reducing tropical glaciers. Glacier volume loss and permafrost thawing will continue in all scenarios (*high confidence*) (Ranasinghe et al., 2021). On average, the tropical Andes have lost about 30% and more of their area since the 1980s (Basantes-Serrano et al., 2016; Mark et al., 2017; Thompson et al., 2017; Rabatel et al., 2018; Vuille et al., 2018; Reinthaler et al., 2019a; Seehaus et al., 2019; Masiokas et al., 2020). In a low emissions scenario, by the end of the 21st century, Peru will lose about 50% of the present glacier surface, while in a high-emission scenario there will remain very small areas of only about 3–5% on the highest peaks (Schauwecker et al., 2017).

Changing glaciers, snow and permafrost (Figure 12.13), in synergy with land use change, have implications for the occurrence, frequency and magnitude of derived floods and landslides (*high confidence*) (Huggel et al., 2007; Iribarren Anacona et al., 2015; Emmer, 2017; Mark et al., 2017). Also to landscape transformation through lakes' formation or drying, and to alteration of hydrological dynamics, with impacts on water for human consumption, agriculture, industry, hydroelectric generation, carbon sequestration and biodiversity (*high confidence*) (Michelutti et al., 2015; Carrivick and Tweed, 2016; Kronenberg et al., 2016; Emmer, 2017; Mark et al., 2017; Milner et al., 2017; Polk et al., 2017; Reyer et al., 2017; Young et al., 2017; Vuille et al., 2018; Cuesta et al., 2019; Drenkhan et al., 2019; Hock et al., 2019; Motschmann et al., 2020a).

Water flow has decreased in several basins as the Shullcas River in the Cordillera Huaytapallana in Peru and is expected to decrease in the near future in in places such as the Cordillera Blanca in Peru (*very high confidence*) (Baraer et al., 2012; Vuille et al., 2018; Somers et al., 2019; Molina et al., 2020). Disruptions in water flows will significantly degrade or disappear high-elevation wetlands (*high confidence*) (Bury et al., 2013; Dangles et al., 2017; Mark et al., 2017; Polk et al., 2017; Cuesta et al., 2019). Impacts on wetlands are affecting the wild vicuña and the domesticated alpaca (Duchicela et al., 2019). New lakes represent a source of future hazards and water scarcity, as well as an opportunity as water reservoirs (Colonia et al., 2017; Drenkhan et al., 2019). The timing and extent of peak water due to glacier shrinkage is spatially highly variable, and has passed for a large number of tropical Andes glaciers (Hock et al., 2019). Cities dependent on glacier melt have experienced high variability in domestic water supply (Chevallier et al., 2011; Soruco et al., 2015; Mark et al., 2017) as shown in Case Study 2.7.3, but the increase of the demand may also be determinant (Buytaert and De Bièvre, 2012). Water provision is related to socio economic issues (Drenkhan et al., 2015). Glacier retreat impacts Andean pastoralists (*high confidence*), as shown in Case Study 2.6.5.4.

NWS houses several global priority areas for biodiversity conservation, including the Tropical Andes and Tumbes-Chocó-Magdalena terrestrial biodiversity-rich spots (Cross-Chapter Paper 1.2.2; Manes et al., 2021) . Biodiversity in Tropical Andes and Tumbes-Chocó-Magdalena is projected to suffer negative impacts (*medium confidence: medium evidence, high agreement*) (Figure 12.9). Invasive plant species might benefit from climate change in these hotspots (Wang et al., 2017a). Species distribution is changing upslope due to increasing air temperature, leading to range contraction and local extinctions for highland species. Whereas, lowland species are experiencing range contractions at the rear end and expansions in the frontend, including vectors of diseases (*high confidence*) (Crespo-Pérez et al., 2015; Duque et al., 2015; Morueta-Holme et al., 2015; Moret et al., 2016; Aguirre et al., 2017; Cuesta et al., 2017a; Seimon et al., 2017; Fadrique et al., 2018; Tito et al., 2018; Zimmer et al., 2018; Cauvy-Fraunié and Dangles, 2019; Cuesta et al., 2019; Moret et al., 2020; Rosero et al., 2021). Vegetation in summits of the northern Andes is particularly vulnerable because of a high abundance of endemic species with narrow thermal niches, and lowland dispersal capacity in comparison to the Central Andes (Cuesta et al., 2020).

The upper limit of alpine vegetation (*paramo*) shifted upslope 500 m in the Chimborazo (Morueta-Holme et al., 2015). Yet, the upper forest limit (the ecotone between forest and alpine vegetation), is migrating at slower rates, or not migrating at all (Harsch et al., 2009; Rehm and Feeley, 2015b), so it is expected to be a major barrier to migration to several montane species, leading to population reductions and biodiversity losses (Lutz et al., 2013; Rehm and Feeley, 2015a). Shifts in tree species distribution may result in decreased above ground carbon stocks and productivity in tropical mountain forests (*high confidence*) (Feeley et al., 2011; Duque et al., 2015; Fadrique et al., 2018; Duque et al., 2021), a biomass loss that will only be partially offset through increased recruitment and growth of lowland species migrating upslope. Water scarcity can enhance tree mortality and decrease above ground carbon stocks (Álvarez-Dávila et al., 2017; McDowell et al., 2020). Agricultural frontier of crops, as potatoes or maize, is going upwards (*high confidence*), following the freezing level height upward displacement (Morueta-Holme et al., 2015; Skarbø and VanderMolen, 2016; Schauwecker et al., 2017; Vuille et al., 2018). Modelling exercises agree with the observed impacts in species, ecosystem processes, crop impacts and related pests and diseases (*high confidence*) (Cernusak et al., 2013; Tovar et al., 2013; Ramirez-Villegas et al., 2014; Ovalle-Rivera et al., 2015; van der Sleen et al., 2015; Lowe et al., 2017). Agricultural options are changing as a result of intra seasonal temperature variation (Ponce, 2020). Changes in timing and amount of precipitation are also impacting agriculture (Table 12.4; Heikkinen, 2017; Altea, 2020) .

Species distribution is changing in dry lowland forests, where deforestation is the more intense driver and climate change is intensely acting (Aguirre et al., 2017; Manchego et al., 2017). Extinctions in amphibians have been related with temperature raises acting in synergy with diseases (Catenazzi et al., 2014). The fungus *Batrachochytrium dendrobatidis* successfully accompanied and caused disease in high-elevation Andean frogs as they expanded their ranges to reach 5200–5400 m (Seimon et al., 2017). Several groups of freshwater species of the tropical Andes represent 35% of threatened freshwater species in the world (Gardner and Finlayson, 2018). Potential impacts of species turnover in key areas for biodiversity conservation have been identified (Cuesta et al., 2017b).

Climate change related hazards could foster rural poverty, and its impacts have led to the modification of agriculture calendars and irrigation adjustments (Postigo, 2014). Livestock is reducing due to rising temperatures, changing water flows and diminishing of pastures, particularly cattle and pig production (Bayer et al., 2014; Tapasco et al., 2015; Bergmann et al., 2021). In some cases farmers respond to extreme temperatures by increasing use of land and crop intensity (Aragón et al., 2021). Climate change has and will prompt internal and international migrations (Løken, 2019; Bergmann et al., 2021). A change in fire regimes and fire risk is expected in highland ecosystems, although it is difficult to determine the influence of human activities and climate change influence on fire patterns (Oliveras et al., 2014; Oliveras et al., 2018; Armenteras et al., 2020).

12.3.3 Northern South America (NSA) Sub-region

12.3.3.1 Hazards

A significant increase in the intensity and frequency of warm extremes and length of heat waves, and decrease in the frequency of cold extremes (Skansi et al., 2013) was *likely* observed (Figure 12.6; Donat et al., 2013; Almeida et al., 2017; WGI AR6 Table 11.13, Seneviratne et al., 2021). Precipitation showed increasing trends in annual and wet season totals over the eastern part and decreasing trends of the dry season (Almeida et al., 2017). Increase in the frequency of anomalous severe floods (Gloor et al., 2015) was observed but insufficient data coverage for extreme precipitation and trends in available data result in *low confidence* (Avila-Diaz et al., 2020; Dereczynski et al., 2020; Dunn et al., 2020; Sun et al., 2021) (WGI AR6 Table 11.14) (Seneviratne et al., 2021). Droughts presented mixed trends between subregions, but evidences indicate increasing length of dry periods (*low confidence*) (Skansi et al., 2013; Marengo and Espinoza, 2016; Spinoni et al., 2019; Avila-Diaz et al., 2020; Dereczynski et al., 2020; Dunn et al., 2020) (WGI AR6 Table 11.15) (Seneviratne et al., 2021) (WGI AR6 Table 12.3) (Ranasinghe et al., 2021).

An overall increase in temperature by the end of century is projected for all the seasons, from 2 to 6°C depending on the scenario (Chou et al., 2014). Projections also suggest increases in the intensity and frequency of hot extremes and decreases in the intensity and frequency of cold extremes (*very likely* for a 2ºC GWL) (López-Franca et al., 2016) (WGI AR6 Table 11.13) (Seneviratne et al., 2021). In all the region, extreme maximum temperature estimates under the RCP4.5 scenario are projected to increase. Tropical major cities are expected to be strongly affected by heat waves and daily record temperatures (Feron et al., 2019).

A decrease in precipitation over the tropical region but regional changes, such as increases in rainfall amounts in western NSA of up to 40 mm, are expected by mid-century under RCP8.5 (Teichmann et al., 2013; Sánchez et al., 2015). Changes in the dry season in the central part of South America due to the late onset and late retreat of monsoon, decreases in precipitation over the Amazon and central Brazil are expected (Coppola et al., 2014; Giorgi et al., 2014; Llopart et al., 2014). And with *medium confidence*: increase in the frequency and geographic extent of meteorological drought in the eastern Amazon, and the opposite in the west (Duffy et al., 2015). A decreasing of total annual precipitation, but increase in heavy precipitation (Seiler et al., 2013; Chou et al., 2014) are projected for a 2ºC GWL (Figure 12.6; WGI AR6 Table 11.15; Seneviratne et al., 2021).

Mean precipitation will decrease and heavy precipitation, aridity and drought will increase with *medium confidence,* mean temperature, extreme heat, fire weather, coastal and oceanic climate impact drivers all of them will increase with *high confidence* (Sun et al., 2019) (WGI AR6 Table 12.6; WGI AR6 Figure 12.8) (Ranasinghe et al., 2021).

12.3.3.2 Exposure

In NSA the percentage of the national population living in Low Elevation Coastal Zones (LECZ) and exposed to Sea Level Rise (SLR) is 68% for Suriname, 56% for Guyana and 6% Venezuela (Nagy et al., 2019). In these countries, exposure of populations, land areas and built capital to coastal floods is projected to continue and increase (Neumann et al., 2015; Reguero et al., 2015).

In the Amazon basin, approximately 80% of the population is concentrated in cities due to migrations in search of improvements in education, job opportunities, health and goods and services (Eloy et al., 2015; Pinho et al., 2015). These populations settle in areas prone to flooding combined with various levels of sanitation due to limited economic access to areas of lower risk (Pinho et al., 2015; Mansur et al., 2016; Andrade and Szlafsztein, 2018; Parry et al., 2018). In these areas, poor urban planning and high population densities increase exposure levels (Mansur et al., 2016). In this context, 41% of the total population of urban centres, of the Amazon Delta and Estuaries (ADE) are exposed to flooding (Mansur et al., 2016), while in Santarem, population and infrastructure are highly exposed to floods and flash floods (Andrade and Szlafsztein, 2018).

Exposure of the Brazilian Amazon to severe to extreme drought has increased from 8% in 2004/2005, to 16% in 2009/2010 and 16% in 2015/2016 (Anderson et al., 2018b); a similar trend is reported in other regions (Table 12.3). During the extreme drought of 2015/2016 in the Amazonian forests 10% or more of the area showed negative anomalies of the Minimum Cumulative Water Deficit (Anderson et al., 2018b). This extreme drought also caused an increase in the occurrence and spread of fires in the basin (*medium confidence: medium evidence, high agreement*) (Aragão et al., 2018; Lima et al., 2018; Silva Junior et al., 2019; Bilbao et al., 2020).The exposure to anomalous fires in ecosystems such as savannas, more fire-prone, increases the exposure and vulnerability of adjacent forest ecosystems not adapted to fire, such as seasonally flooded forests (Bilbao et al., 2020; Flores and Holmgren, 2021).

12.3.3.3 Vulnerability

NSA is one of the most vulnerable subregions in the region, after CA, as evidenced by its very high vulnerability in four of the six sectors assessed (Figure 12.7). LECZ of Venezuela, Guyana and Suriname are highly vulnerable to climate change due to SLR (*high confidence*) (CAF, 2014; Mycoo, 2014; Reguero et al., 2015; Villamizar et al., 2017; Nagy et al., 2019). In Guyana, the combined effect of increased rainfall intensity and SLR has caused flooding over the past two decades, increasing the vulnerability of the agriculture sector (Tomby and Zhang, 2019).

The unprecedented extreme events of floods (2009, 2012 and 2014) and drought (2010) in the Amazon basin led to increased societies vulnerability (*medium confidence*: *medium evidence, high agreement*) (Mansur et al., 2016; Debortoli et al., 2017; Marengo et al., 2018; Menezes et al., 2018). The disruption of the region natural hydrology dynamics, as a consequence of extreme events increases the sensitivity of the food and transport systems of the Indigenous Peoples and rural resource-dependent communities (Pinho et al., 2015).

Migration by Indigenous Peoples and rural resource-dependent communities to cities have increased due to urbanization, development of extractive activities, agroindustry and infrastructure. Upon migrating, they are forced to abandon their livelihoods in order to acquire temporary jobs and to live in poverty and exclusion conditions on the periphery of the city (Cardoso et al., 2018). Between 60–90% of the population in the urban centres of ADE live in conditions of moderate to high degree of vulnerability (Mansur et al., 2016) (Figure 12.7). Amazon populations located in remote urban centres with limited or non-existing roads are more vulnerable to extreme events in relation to more connected urban centres (Parry et al., 2018). These highly vulnerable circumstances reduce the adaptive capacity of these populations (Cardoso et al., 2018). Nevertheless, the dynamics of the adaptive capacity of the Indigenous Peoples and rural resource-dependent communities is a complex issue. There is robust and growing literature showing that resource-dependent communities located in remote areas, address climate anomalies by reducing the vulnerability of socio-ecological systems through Indigenous knowledge and local knowledge (*high confidence*) (Mistry et al., 2016; Vogt et al., 2016; Bilbao et al., 2019; Bilbao et al., 2020; Camico et al., 2021).

Amazonian forests constitute one of the major carbon (C) sinks on Earth (Pan et al., 2011), playing a pivotal role in the climate system and regional balance of C and water (Marengo et al., 2018; Molina et al., 2019). Deforestation, temperature increase and any factor affecting the forests ecosystem dynamics will have an impact on the atmospheric CO_2 concentration and hence on the global climate (Ruiz-Vásquez et al., 2020; Sullivan et al., 2020).There is robust scientific evidence of the high vulnerability of the Amazonian forests to increasing temperature and repeated extreme drought events (*high confidence*) (Figure 12.7; Brienen et al., 2015; Olivares et al., 2015; Feldpausch et al., 2016; Zhao et al., 2017; Anderson et al., 2018b; Anjos and De Toledo, 2018; Yang et al., 2018; Barkhordarian et al., 2019; Sampaio et al., 2019; Rammig, 2020; Sullivan et al., 2020) .

12.3.3.4 Impacts

Suriname has experienced coastal erosion and flooding, causing damage to infrastructure, agriculture and ecosystems while Georgetown has suffered a significant number of floods (CAF, 2014). In Guyana, coastal flooding has negatively impacted agricultural activity (Tomby and Zhang, 2018) (Figure 12.9). Sugarcane production has been one of the most impacted cash-crops. The impact on sugar production has affected Guyana's sugar industry (Tomby and Zhang, 2019). Among the main impacts observed in the sugar industry are an increase in production costs, greater use of pesticides and fertilizers, and a reduction in workers' income (Tomby and Zhang, 2018).

Indigenous Peoples and resource-dependent rural communities in the Amazon have been impacted over the last decade by extreme drought and flood events in various dimensions of their livelihoods (Pinho et al., 2015). Food security has been strongly impacted since it is based on fishing and small-scale agriculture, two sectors highly vulnerable to climate change. During extreme events, fishing decreases due to limited access to fishing grounds (*medium confidence*: *low evidence, high agreement*) (Figure 12.9; Pinho et al., 2015; Camacho Guerreiro et al., 2016. Overfishing, deforestation and dam construction are a threat to fishing in the subregion (Lopes et al., 2019) and therefore contribute to exacerbating the impacts of climate change. Small scale agriculture practices (e.g., floodplain agriculture and slash and burn), are highly coupled with natural hydrological cycles and therefore severely affected by extreme events (Figure 12.9; Cochran et al., 2016. Livelihoods are also impacted by disruptions in land and river transport, restrictions in drinking water access, increased incidence of forest fires and disease outbreaks (*medium confidence*: *medium evidence, high agreement*) (Figure 12.9; Marengo et al., 2013; Pinho et al., 2015; Marengo and Espinoza, 2016; Marengo et al., 2018). In addition, flood events have caused losses of homes and disruption of public and commercial services (Figure 12.9; Parry et al., 2018).

Several vector-driven diseases such as malaria and leishmaniasis are endemic of Amazon region, however socio-environmental changes are altering their natural dynamics (Confalonieri et al., 2014b). An important relationship between the outbreak of infectious diseases and changes in climatic events (e.g., droughts, floods, heat waves, ENSO) or environmental events (e.g., deforestation, dam construction and habitat fragmentation) have been found for the Brazilian Amazon (*medium confidence*: *medium evidence, high agreement*) (Pan et al., 2014; Filho et al., 2016; Nava et al., 2017; Ellwanger et al., 2020). These impacts are more severe in poor populations with limited access to health services (Pan et al., 2014; WHO and UNFCCC, 2020). In the case of Venezuela, the impact of climate change on the epidemiology of malaria has been studied, showing significant influence on transmission in the Amazonia area of the country (Figure 12.4; Laguna et al., 2017) . Other studies from Venezuela have documented the role of ENSO in dengue outbreaks (Vincenti-Gonzalez et al., 2018). Table 12.1 shows the changes observed in reproduction potential for dengue in the different subregions due to changes in rainfall and temperature. Forest fires are a major concern to public health in the region as they relate to an increase in hospital admissions due to respiratory problems, mainly among children and the elderly (Figure 12.5). The amount of air pollutants detected is sometimes higher than that observed in large urban areas, especially during dry seasons when biomass burning increases (Aragão et al., 2016; de Oliveira Alves et al., 2017; Paralovo et al., 2019).

Table 12.1: Environmental suitability for the transmission of dengue by *Aedes aegypti* as modelled by the influence of temperature and rainfall on vectorial capacity and vector abundance; this is overlaid with human population density data to estimate the reproduction potential for these diseases (R_0, the expected number of secondary infections resulting from one infected person). The Southwest South America (SWS) and Southern South America (SSA) subregions are not presented, as the vector is not abundant in these areas and the estimated R_0 is lower than 0.01. Data derived from Romanello et al. (2021).

Subregion	Average R_0 1950-1954	Average R_0 2016-2020	Absolute change in R_0 from 1950-54 to 2016-20	% change in R_0 from 1950-54 to 2016-21
Central America (CA)	3.00	3.53	0.53	18%
Northwest South America (NWS)	1.85	2.40	0.55	30%
Northern South America (NSA)	1.31	2.05	0.74	56%
South America Monsoon (SAM)	0.93	1.67	0.74	80%
Northeast South America (NES)	2.11	2.47	0.36	17%
Southeast South America (SES)	0.64	0.81	0.17	26%

Climate change impacts have also been observed in ocean, coastal ecosystems (coral reefs and mangroves), Exclusive Economic Zones (EEZ) and saltmarshes in NSA; further impacts are expected in coral reefs, estuaries, mangroves and EEZs in the sub-region (Figure 12.9). Species in freshwater ecoregions (e.g., the Orinoco and Amazon Rivers and their flooded forests) are predicted to suffer a decrease in range and climatic suitability (*medium confidence: low evidence, high agreement*) (Cross-Chapter Paper 1.2.3; Manes et al., 2021) . A significant decrease in climate refugia (90%) for multiple vertebrate and plant species in the region has been projected for a 4ºC scenario, with considerable benefits of mitigation and reducing risks to 40% for a 2ºC scenario (Warren et al., 2018).

Droughts in 2009/2010 and 2015/2016 increased tree mortality rate in Amazon forests (Doughty et al., 2015; Feldpausch et al., 2016; Anderson et al., 2018b), while productivity didn't show a consistent change; some authors report a drop in productivity (Feldpausch et al., 2016) and others found no significant changes (Brienen et al., 2015; Doughty et al., 2015). Nevertheless the combined effect of increasing tree mortality with variations in growth, results in a long-term decrease in C stocks in forest biomass compromising their role of these forests as C sink (*high confidence*) (Brienen et al., 2015; Rammig, 2020; Sullivan et al., 2020) (Figure 12.9). Under the RCP8.5 scenario for 2070, drought will increase the conversion of rainforest to savannahs (*medium confidence*: *medium evidence, high agreement*) (Anadón et al., 2014; Olivares et al., 2015; Sampaio et al., 2019). The transformation of rainforest into savannahs brings forth biodiversity loss and alterations in ecosystem functions and services (*medium confidence*: *medium evidence, high agreement*) (Anadón et al., 2014; Olivares et al., 2015; Sampaio et al., 2019). In the Amazon basin, the synergic effects of deforestation, fire, expansion of the agricultural frontier, infrastructure development, extractive activities, climate change and extreme events may exacerbate the risk of savannisation (*medium confidence*: *medium evidence, high agreement*) (Nobre et al., 2016b; Bebbington et al., 2019; Sampaio et al., 2019; Rammig, 2020).

12.3.4 South America Monsoon (SAM) Sub-region

12.3.4.1 Hazards

Temperature extremes have *likely* increased in the intensity and frequency of hot extremes and decrease in the intensity and frequency of cold extremes (Donat et al., 2013; Bitencourt et al., 2016) (WGI AR6 Table 11.13) (Seneviratne et al., 2021). In a vast transition zone between the Amazon and the Cerrado Biomes within the region, analysis of seasonal precipitation trends suggested that almost 90% of the observational sites showed reduced in the length of the rainy season in the region (Debortoli et al., 2015), on a period from 1971 to 2014 (Marengo et al., 2018), confirming the growth in length of the dry season. Changes in the hydrological and precipitation regimes, characterized by reduction in rainfall in Southern Amazonia, contrasting to an increase in the northwest Amazonia, and overall increases in extreme precipitation and in the frequency of Consecutive Dry Days, is being reported by several authors (Fu et al., 2013; Almeida et al., 2017; Marengo et al., 2018; Espinoza et al., 2019a) with *low confidence* (WGI AR6 Table 11.14; Seneviratne et al., 2021) due to insufficient data coverage and trends in available data generally not significant.

The Amazon has been identified as one of the areas of persistent and emergent regional climate change hotspots in response to various representative concentration pathways (Diffenbaugh and Giorgi, 2012). In Bolivia, CMIP3/5 models projected an increase in temperature (2.5ºC–5.9ºC), with seasonal and regional differences. In the lowlands, both ensembles agreed on less rainfall (–19%) during drier months (June–August and September–November), with significant changes in inter-annual rainfall variability, but disagreed on changes during wetter months (January–March) (Seiler et al., 2013). As a consequence of higher temperatures and reduced rainfall, an increased water deficit would be expected in the Brazilian Pantanal (Marengo et al., 2016; Bergier et al., 2018; Llopart et al., 2020) with *high confidence*. The largest increases in warmer days and nights, and aridity, drought and significant increases in fire occurrence are calculated over the Amazon area (Huang et al., 2016). Over all the region, by mid-century (RCP4.5) there is *medium confidence* of increase of river and pluvial floods, aridity and mean wind speed, and extreme heat, fire weather and drought are projected to increase with *high confidence* (WGI AR6 Table 12.6; Ranasinghe et al., 2021).

12.3.4.2 Exposure

A large expansion in cropland area (soybean, corn and sugarcane) was observed in the past two decades in SAM, in response to an increased local and global demand for biofuels and agricultural commodities (*high confidence*) (Lapola et al., 2014; Cohn et al., 2016). Feedbacks to the climate system resulting from such land-use changes are intricate. The clear-cutting of Amazon forest and Cerrado savannah in the region lead to a local warming due to an increase in the energy balance and evapotranspiration (Malhado et al., 2010), contrastingly the replacement of pasture by agriculture leads to local cooling effect, due to changes in the surface albedo (*medium confidence: medium evidence, medium agreement*). Deforestation of the Amazon for pastures and soybean have decreased evapotranspiration during drought months and caused a localized lengthening of the dry season in Northwest SAM by 6.5 (± 2.5) days since 1979 (*medium confidence: medium evidence, medium agreement*) (Fu et al., 2013).

It is not surprising therefore that while SAM is the region in CSA that experienced the highest temperature increase in the last century, it is where most of the fire spots in the sub-continent are located, owing also to the prevalent use of fires in pasture lands (*medium confidence: medium evidence, high agreement*) (Bowman et al., 2009). Recently, da Silva Junior et al. (2020) reported 6,708,350 and 6,188,606 fire foci in Cerrado and Amazonia, between 1999 and 2018, corresponding to 80% of the total observed in Brazil. The occurrence of extreme droughts has affected the carbon and water cycles in large areas of the Amazon Forest (*high confidence*) (Lapola et al., 2014; Agudelo et al., 2019), in particular in its southern and eastern portions, where deforestation rates are higher. The loss of carbon in the Amazon region considering the combined effect of land use change in the southern portion of the region, bordering Cerrado and Pantanal, and global carbon emission scenarios, can be up to 38% at 4ºC of warming, but limited to 8% if the Paris agreed limit of 1.5°C is achieved (*medium confidence, medium evidence, high agreement*) (Burton et al., 2021), driving the region to be a net carbon source to the atmosphere (Gatti et al., 2021). A recent extreme drought was estimated to affect the photosynthetic capacity of 400,000 km^2 of the forest (Anderson et al., 2018b), nevertheless there are considerable uncertainties regarding the effects of CO_2 fertilization in tropical forests and ecosystems (*medium confidence: medium evidence, high agreement*) (Sampaio et al., 2021). Extreme drought events increase forest vulnerability to fire, directly affecting the biodiversity, the forest structure and its plant species distribution (*high agreement*) (Brando et al., 2014). Production sectors are also exposed. SAM is pointed out as a region where agricultural production will be especially impacted by climate change, affecting production of annual crops, fruits and livestock (*medium confidence: medium evidence, high agreement*) (Lapola et al., 2014; Zilli et al., 2020).

12.3.4.3 Vulnerability

The largest expanses of remaining vegetation in the Cerrado biome are located in SAM, but the region shows low number of protected areas (only 7.5% inside protected areas), which will leave fauna and flora with little room for moving across the landscape in the face of climate change. Protected areas —Indigenous lands included— have markedly detained forest clear-cutting in the Amazon deforestation arc (most of which is inside SAM) (*high confidence*) (Nolte et al., 2013). However nearly one hundred protected areas in the Amazon, Cerrado and Pantanal biomes inside SAM have been identified as highly or moderately vulnerable to future climate change and demand deep adaptation interventions (*medium confidence: medium evidence, high agreement*) (Feeley and Silman, 2016; Lapola et al., 2019b). Yet, the maintenance of these protected areas or even the halting of deforestation may do little to impede a large-scale ecosystem shift, persistently, to an alternative state (crossing a tipping point) of the Amazon forest or even more subtle changes caused by climate change in the region (*medium confidence: medium evidence, high agreement*) (Aguiar et al., 2016a; Boers et al., 2017; Lapola et al., 2018; Lovejoy and Nobre, 2018).

The agriculture in the region is highly dependent on the climate (*high confidence*), responsible for ¾ of the variability in agricultural yields in the region (Table 12.4). Irrigation is an important strategy for agriculture production in part of the region, nevertheless not accounting to more than 8% of the total agricultural area in South America and 7% in Central America (OECD and FAO, 2019). This practice faces potential impacts from reduction in surface water availability in future climate scenarios (Ribeiro Neto et al., 2016; Zilli et al., 2020), enhanced by non-climate drivers such as land use changes (*medium confidence: medium evidence, high agreement*) (Spera et al., 2020). The remaining fluctuation on yields relates to issues of infrastructure, market, economy, policy and social aspects. Good infrastructure, transport logistics, quality of roads and storage, strongly influences the vulnerability of the agriculture sector (Figure 12.7).

The combined effect of extreme climate events and ecosystem fragmentation, e.g., by deforestation or fire, lead to changes in forest structure, with the death of taller trees and reduction in diversity of plant species, loss of productivity and carbon storage (*high agreement*) (Brando et al., 2014; Reis et al., 2018). The rise of the large-scale soybean agroindustry in the early 2000's led to a faster increase in human development indicators in some regions, tightly linked to the agricultural production chain (*high confidence*) (Richards et al., 2015). Such a development also came at a considerable cost for the environment (e.g., Neill et al. (2013)) and the regional climate, even though a moratorium implemented in 2006 to refrain new soy plantations on deforested areas reduced deforestation by a factor of five (*high confidence*) (Macedo et al., 2012; Kastens et al., 2017). The same sort of supply chain interventions along with incentive-based public policies applied to the beef supply chain could minimize the need for agricultural expansion in the SAM deforestation frontier (*medium confidence: medium evidence, high agreement*) (Nepstad et al., 2014; Pompeu et al., 2021).

SAM has a low population density, and the majority of population is located in cities. The population of some of these cities are indicated as highly vulnerable considering the enormous social inequalities embedded in these cities (*high confidence*) (Filho et al., 2016). Inequalities and uneven access to infrastructure, housing and health support, increase population vulnerability to atmospheric pollution and drier conditions (*high confidence*) (Rodrigues et al., 2019; IPAM, 2020; Machado-Silva et al., 2020).

12.3.4.4 Impacts

The Amazon and the Cerrado are amongst the largest and unique phytogeographical domains in South America. The Brazilian Cerrado is amongst the richest biodiversity in the world, with more than 12,600 plant species, being 35% endemic (*high confidence*) (Forzza et al., 2012). Historic land cover change and concurrent climate change in the region strongly impacted the biodiversity and led to the extinction of 657 plant species for the Cerrado, which is more than four-fold the global recorded plant extinctions (*high confidence*) (Strassburg et al., 2017; Green et al., 2019). Effects of climate change, expressed by drought and heat waves, lead to plant stress, compromising growth and increasing mortality (Yu et al., 2019). The fauna dependent on dew water was strongly impacted due to a temperature rise of 1.6ºC from 1961 to 2019 (*medium confidence: medium evidence, medium agreement*) (Hofmann et al., 2021). Modelling outcomes project impacts in forest ecosystems in the region, with persistent warming and significant moisture reduction (Anjos et al., 2021), leading to a potential change in the ecosystem structure and distribution in the region (*medium confidence: medium evidence, medium agreement*) (Government of Brazil, 2020).

The observed impact on plant species in SAM is projected to worsen in a warmer world (Warszawski et al., 2013). An increasing dominance of drought-affiliated genera of tree species has been reported in the southern part of the Amazon forest in the last 30 years (*medium confidence: medium evidence, medium agreement*) (Esquivel-Muelbert et al., 2019). Due to the tight relation of drought and fire occurrence, an increase of 39 to 95% of burned area is modelled to impact the Cerrado region under RCP4.5 and RCP8.5, while under RCP2.6, a 22% overshoot in temperature is estimated to impact the area in 2050 decreasing to 11% overshoot by 2100 (Silva et al., 2019d), leading to high impact on agriculture production (*high confidence*).

SAM hosts the headwaters of important SA rivers such as the Paraguay, Madeira, Tocantins-Araguaia and Xingu. The impact from climate change is expressed differently among several sub-regions. Extreme floods in Southern Amazon and Bolivian Amazon floodplains were described and related to exceptionally warm subtropical South Atlantic ocean (*high confidence*) (Espinoza et al., 2014), causing high economic impact (losses in crop and livestock production and infrastructure) and number of fatalities (*very high confidence)* (Ovando et al., 2016). Contrastingly, decline in stream flow, particularly in the dry season, expressed by the ratio between runoff and rainfall, is observed for the southern part of the Amazon basin (*high evidence*) (Molina-Carpio et al., 2017; Espinoza et al., 2019b; Heerspink et al., 2020). Observed precipitation reduction in the Cerrado region impacted main water supply reservoir for important cities in the Brazilian central region, leading to a water crisis in 2016/2017 (Government of Brazil, 2020) and affecting energy hydropower generation (Ribeiro Neto et al., 2016). Modelling studies project decreases in river discharge rate in the order of 27% for the Tapajós basin and 53% for the Tocantins-Araguaia basin for the end of the century, which may affect freshwater biodiversity, navigation and generation of hydroelectric power (*medium confidence: medium evidence, high agreement*) (Marcovitch et al., 2010; Mohor et al., 2015). This region also holds one of the largest floodplains in the globe, the Pantanal. The climatic connection of Pantanal regions to the Amazon, and the influence of deforestation in local precipitation (Marengo et al., 2018) has implications for conservation of ecosystem services and water security in Pantanal (*high confidence*) (Bergier et al., 2018). Impacts of extreme drought, with increasing numbers of dry days, and peak of fire foci was recently reported (*robust evidence*) (Lázaro et al., 2020; Garcia et al., 2021). Projected impacts of climate change shall lead to profound changes in the annual flood dynamics for the Pantanal wetland, altering ecosystem functioning and severely affecting biodiversity (*high confidence*) (Thielen et al., 2020; Marengo et al., 2021)

Soybean and corn yields, in the Cerrado region, will suffer one of the strongest negative impacts under RCP4.5 and RCP8.5 scenarios estimate and will demand high investments for adaptation should it continue to be cultivated in the same localities as today (*high confidence*) (Oliveira et al., 2013; Camilo et al., 2018). Changes in precipitation patterns were related to reduction of agriculture productivity and revenues in the southern portion of the Amazon region (*medium confidence: medium evidence, high agreement*) (Costa et al., 2019; Leite-Filho et al., 2021). As such, the future socio-economic vigour of the region will be, to a large extent, connected to an unlikely stability of the regional climate and eventual fluctuations of global markets potentially affecting the agricultural supply chain (*high confidence*) (Nepstad et al., 2014).

Observations from recent past droughts in SAM indicates how the incidence of respiratory diseases may worsen under a drier and warmer climate. Northwest SAM had a ~54% increase in the incidence of respiratory diseases associated with forest fires during the 2005 drought compared to a no-drought 10-year mean (*high confidence*) (Ignotti et al., 2010; Pereira et al., 2011; Smith et al., 2014). It is estimated that more than 10 million people are exposed to forest fires in the deforestation arc, a region comprising several Brazilian states in the southern and western parts of the Amazon forest, with several impacts on human health including potential exacerbation the COVID-19 crisis in Amazonia (*medium confidence: medium evidence, high agreement*) (de Oliveira et al., 2020) (Table 12.5). Increases in hospital admissions, asthma, DNA damage and lung cell death due to inhalation of fine particulate matter, represents an increase in public health system costs (*high confidence*) (Ignotti et al., 2010; Silva et al., 2013; de Oliveira Alves et al., 2017; Machin et al., 2019).The patchy landscape created by forest clearing contribute to a rising risk of zoonotic disease emergence by increasing interactions between wildlife, livestock and humans (*medium confidence: low evidence, medium agreement*) (Dobson et al., 2020; Tollefson, 2020). Recent studies also suggested the influence of climate change in zoonotic diseases, such as Orthohantavirus and Chapare virus infections, rodent-borne diseases, in some areas of Bolivia (Escalera-Antezana et al., 2020a; Escalera-Antezana et al., 2020b). Extreme fluctuation in the river level in the amazon was associated to a significant increase in the incidence of diarrhoea, leptospirosis and dermatitis (de Souza Hacon et al., 2019; Government of Brazil, 2020). A comprehensive characterization of future heatwaves, and alternative RCPs scenarios, Brazilian urban areas at SAM region are projected to face increasing related mortality from 400 to 500% in the period from 2031 to 2080 compared to the period of 1971–2020, under the highest emission scenario and high-variant population scenario (*medium confidence: low evidence, medium agreement*) (Guo et al., 2018). Table 12.2 shows the increase in days of exposure to heatwaves already observed in the region.

Table 12.2: Average change in the mean number of days exposed to heatwaves (defined as a period of at least two days where both the daily minimum and maximum temperatures are above the 95th percentile of their respective climatologies) in the population over 65 years of age in 2016-2020 relative to 1986-2005. Temperature data taken from the European Centre for Medium-Range Weather Forecasts (ECMWF) ERA5 dataset; calculations derived from Romanello et al. (2021).

Country	Number of additional days of heatwave exposure in 2016-2020 relative to 1986-2005
Argentina	4.9
Belize	8.8
Bolivia	2.2
Brazil	3.1
Chile	3.3
Colombia	9.3
Costa Rica	0.8
Ecuador	7.6
El Salvador	2.2
Guatemala	8.4
Guyana	8.2
Honduras	11.2
Nicaragua	2.2
Panama	2.6
Paraguay	2.6
Peru	3.6
Suriname	15.2
Uruguay	2.7
Venezuela	8.5

The high risk of floods (high-frequency and high-incurred damage) is centred in the Brazilian states of Acre, Rondônia, Southern Amazonas and Pará (Andrade et al., 2017). Global-scale studies indicate an increase of flood risk for the SAM region during the 21st century (consistent with floods that are more frequent) (*high confidence*) (Hirabayashi et al., 2013; Arnell et al., 2016; Alfieri et al., 2017). Higher emission scenarios result in substantially higher flood risks than low emission scenarios (Alfieri et al., 2017).

12.3.5 Northeast South America (NES) Sub-region

12.3.5.1 Hazards

The region has *likely* experienced an increase in temperature, with significant increases in the intensity and frequency of hot extremes and significant decreases in the intensity and frequency of cold extremes (Donat et al., 2013) (WGI AR6 Table 11.13, Seneviratne et al., 2021).

A decrease in the frequency and magnitude of extreme precipitation was observed but with *low confidence*, due to insufficient data coverage and trends in available data generally not significant. An increase in drought duration was observed with *high confidence* but *medium confidence* on the increase of drought intensity (WGI AR6 Table 11.14, Seneviratne et al., 2021). Table 12.3 shows the estimates of changes in land area per subregion affected by drought events, being this subregion which presented the highest changes in CSA.

Table 12.3: Change in the percentage of land area affected by extreme drought in 2010-19, with respect to 1950-59 using the Standardised Precipitation-Evapotranspiration Index (SPEI); extreme drought is defined as SPEI ≤ -1.6 (Federal Office of Meteorology and Climatology MeteoSwiss, 2021). Data derived from Romanello et al. (2021).

	Average change in the percentage of land area in drought in 2010-19 with respect to 1950-59		
Subregion	**At least 1 month in drought**	**At least 3 months in drought**	**At least 6 months in drought**
Central America (CA)	38.8%	17.6%	6.1%
Northwest South America (NWS)	51.8%	25.3%	7.0%
Northern South America (NSA)	52.5%	18.3%	2.5%
South America Monsoon (SAM)	48.0%	34.4%	12.2%
Northeast South America (NES)	64.5%	38.4%	12.0%
Southeast SouthAmerica (SES)	16.4%	6.7%	0.4%
Southwest South America (SWS)	20.5%	13.9%	7.5%
Southern South America (SSA)	-23.5%	-8.8%	--

The projected warming for the extreme annual maximum temperatures over NES is TXx: +2°C for the 1.5°C scenario and about +2.5°C for 2°C scenario (Hoegh-Guldberg et al., 2018). An increased number of tropical nights with minimum temperatures exceeding the 20°C threshold is projected (Orlowsky and Seneviratne, 2012). In general, extreme heat will increase and cold spells decrease with *high confidence*. A decrease in total precipitation is projected with *high confidence* with an increase in heavy precipitation events and an increase in dryness (*medium confidence*). Increase in drought severity due to the combination of increased temperatures, less rainfall, and lower atmospheric humidity (5 to 15% relative humidity reduction) create water deficits, projected for the entire region after 2041 (3–4 mm day^{-1} reduction), particularly over western NES and over the semiarid region (Marengo and Bernasconi, 2015; Marengo et al., 2017). Fire will significantly increase (*high confidence*) (Figure 12.6).

12.3.5.2 Exposure

NES is home to about 60 million people (estimate from IBGE (2019)), with >70% living in urban areas (data from IBGE (2010); Silva et al. (2017)), and high poverty levels (> 50%, data from IBGE (2003)). People are exposed to intense drought and famine (*high confidence*), and about 94% of the region has moderate to high susceptibility to desertification (Marengo and Bernasconi, 2015; Spinoni et al., 2015; Vieira et al., 2015; Mariano et al., 2018; Tomasella et al., 2018; Marengo et al., 2020c). The most severe dry spell of 2012–2013 affected about 9 million people, which were exposed to water, food and energy scarcity (Marengo and Bernasconi, 2015).

People, infrastructure and economic activities are exposed to sea level rise in the 3800 km of coastline (*medium confidence*). The high concentration of cities on the coast is a concern (Martins et al., 2017), with all state capital cities but one on the coast, totalling almost 12 million exposed people (estimate from IBGE (2019)). The ports of São Luís, Recife and Salvador are important exporters of Brazilian commodities, and the beaches in the subregion are an international touristic destination, producing considerable revenues (Pegas et al., 2015; Ribeiro et al., 2017).

Natural systems in NES are also exposed to climate change. In terrestrial ecosystems, 913,000 km^2 of NES' dry forest Caatinga vegetation (Silva et al., 2017) is exposed to predicted increase in dryness. Despite what has been previously suggested, the Caatinga has high biodiversity and endemism (Silva et al., 2017), which is exposed to habitat reduction due to climate change and agriculture expansion (Silva et al., 2019b). Fifty-two percent of the freshwater fish (203 species) are endemic (Lima et al., 2017) and are exposed to predicted reduction in river flow due to climate change (Marengo et al., 2017; de Jong et al., 2018). The coastal waters contain a separate marine ecoregion due to its uniqueness (Spalding et al., 2007). The region is responsible for 99% of the Brazilian shrimp production, exposed to sea level rise and increases in ocean temperature and acidification (Gasalla et al., 2017). Most coral reefs in the Southern Atlantic Ocean are along NES's coast (Leão et al., 2016), increasing its conservation and touristic value. The 685 km^2 of coral reefs along NES's coast (likely underestimated - Moura et al. (2013); UNEP-WCMC et al. (2018)) are exposed to increased sea temperatures.

12.3.5.3 Vulnerability

NES is the world's most densely populated semi-arid land and its population is highly vulnerable to droughts (*high confidence*), which have well-documented impacts on water and food security, human health and well-being in the region (e.g., Confalonieri et al. (2014a); Marengo et al. (2017); Bedran-Martins et al. (2018)) (Figure 12.7). The region's relative low economic development and poor social and health indicators increase vulnerability, especially of poor farmers and traditional communities (Confalonieri et al., 2014a; Bech Gaivizzo et al., 2019). In state capital cities, about 45% of the population live in poverty (data from IBGE (2003)), often in slums with already deficient water supply and sewage systems and poor access to health and education. Climate change will increase pressures on water availability, threatening water, energy and food security (Marengo et al., 2017).

Natural systems in NES are also vulnerable (Figure 12.7). The Caatinga vegetation is particularly sensitive to variations in water availability and climate change (Seddon et al., 2016; Rito et al., 2017; Dantas et al., 2020). It has already lost about 50% of its original vegetation cover (Souza et al., 2020), with only about 2% of the remaining vegetation within fully protected areas (CNUC and MMA, 2020). Caatinga's high vulnerability to climate change is further increased by the extensive conversion of native vegetation (*high confidence*) (Rito et al., 2017; Silva et al., 2019b; Silva et al., 2019c).

Studies with terrestrial animals show that habitat loss increases the vulnerability of species to climate change (*high confidence*) (de Oliveira et al., 2012; Arnan et al., 2018; da Silva et al., 2018b). NES' coral reefs have shown some resilience to bleaching, but vulnerability is intensified by the synergism between chronic heat stress caused by increased sea surface temperature (Teixeira et al., 2019) and other well-documented stressors, such as coastal runoff, urban development, marine tourism, overexploitation of reef organisms and oil extraction (*high confidence*) (Figure 12.8; Leão et al., 2016).

12.3.5.4 Impacts

Impacts of intense drought have been reported in NES since 1780, with severe losses in agricultural production, livestock death, increase in agricultural prices, and human death (Figure 12.9; Marengo et al., 2017; Martins et al., 2019; Government of Brazil, 2020; Marengo et al., 2020c; Silva et al., 2020) (). The rural population already suffers from natural water scarcity in the countryside. In 2012, the drought was responsible for reducing up to 99% of the corn production in Pernambuco state (Government of Brazil, 2020). A predicted increase in drought, coupled with inadequate soil management practices by small farmers and agribusiness, increases the region's susceptibility to desertification (Spinoni et al., 2015; Vieira et al., 2015; Mariano et al., 2018; Tomasella et al., 2018; Marengo et al., 2020c). In NES, 70,000 km^2 have reached a point at which agriculture is no longer possible (Government of Brazil, 2020). Intense droughts has triggered migration to urban centres in and outside NES (Confalonieri et al., 2014a; Government of Brazil, 2020). More than 10 million people have been impacted by the drought of 2012/14 in the region, which was responsible for water shortage and contamination, increasing death by diarrhoea (Marengo and Bernasconi, 2015; Government of Brazil, 2020).

There is growing evidence on the impacts of climate change on human health in NES, mostly linked to food and water insecurity caused by recurrent long droughts (e.g., gastroenteritis and hepatitis) (*high confidence*) (Figure 12.9; Sena et al., 2014; de Souza Hacon et al., 2019; Marengo et al., 2019; Government of Brazil, 2020; Salvador et al., 2020) . From 2071 to 2099, thermal conditions in NES might improve for vectors of dengue, chikungunya and Zika (de Souza Hacon et al., 2019). Additionally, a high risk of mortality associated with climatic stress in the period 2071–2099 is expected in São Francisco river basin (de Oliveira et al., 2019; de Souza Hacon et al., 2019).

Recent studies predict strong negative impact of climate change on NES' agriculture (*high confidence*) (Ferreira Filho and Moraes, 2015; Nabout et al., 2016; Gateau-Rey et al., 2018) (Figure 12.9; Table 12.4). NES concentrates the bulk of the predicted loss of regional gross domestic product associated with agriculture in Brazil (Ferreira Filho and Moraes, 2015; Forcella et al., 2015). Although agriculture gives a modest contribution to the regions' economy, its drop could have a severe impact on the poorest rural household, by shrinking the agricultural labour market and increasing food prices (Ferreira Filho and Moraes, 2015; Government of Brazil, 2020). Expected increase in dryness is also predicted to impact the region's hydroelectric power generation (Marengo et al., 2017; de Jong et al., 2018). Sea level rise has also been reported to impact coastal cities such as Salvador, destroying urban constructions (Government of Brazil, 2020). Sea level rise, increased ocean temperature and acidification may also negatively impact NES's shrimp aquaculture production (Figure 12.8; Gasalla et al., 2017) . Along with climate change, overfishing has driven exploited marine fish species to collapse (Verba et al., 2020).

Biodiversity in NES is highly threatened by climate change in terrestrial (*medium confidence: medium evidence, high agreement*) and freshwater (*low confidence: low evidence, high agreement*) ecosystems (Figure 12.9). There are few studies projecting the likely impact of climate change on NES' biodiversity, especially on its endemic freshwater fish. Recent studies have already reported the reduction in several endemic plant species affecting pollination and seed dispersal (Bech Gaivizzo et al., 2019; Cavalcante and Duarte, 2019; Silva et al., 2019b). Studies with terrestrial animals predict that most groups would be negatively impacted by climate change (de Oliveira et al., 2012; Arnan et al., 2018; da Silva et al., 2018b; Montero et al., 2018). Changes in the abundance of coral reef community and extreme reduction in coral cover have been observed in NES (de Moraes et al., 2019; Duarte et al., 2020). A number of observed coral bleaching events associated with abnormal increase in sea temperatures have occurred in NES (Krug et al., 2013; Leão et al., 2016; de Oliveira Soares et al., 2019) (Figure 12.8), but thus far mortality remained low and corals have been able return to normal values or remain stable after sea water temperature rise (*medium confidence: medium evidence, high agreement*) (Leão et al., 2016). Mangroves in the region have shown increased mortality, but have also expanded their range inland (Figure 12.6; Godoy and Lacerda, 2015; Cohen et al., 2018) . Future projections include mangrove landward expansion and lower migration rates by 2100 (Cohen et al., 2018).

12.3.6 Southeast South America (SES) Sub-region

12.3.6.1 Hazards

The increase in the intensity and frequency of hot extremes and decrease in the intensity and frequency of cold extremes was observed with *high confidence* (Rusticucci et al., 2017; Wu and Polvani, 2017) (WGI AR6 Table 11.13) (Seneviratne et al., 2021). There is *low confidence* that the decrease in hot extremes over SES is related with an increase of extreme precipitation (Wu and Polvani, 2017).

Over SES most of the stations have registered an increase in annual rainfall, largely attributable to changes in the warm season; this is one of few sub-regions where a robust positive trend in precipitation and significant intensification of heavy precipitation has been detected since the beginning of the 20th century (*high confidence*) but with *medium confidence* in a reduction of hydrological droughts (Vera and Díaz, 2015; Saurral et al., 2017; Lovino et al., 2018; Avila-Diaz et al., 2020; Carvalho, 2020; Dereczynski et al., 2020; Dunn et al., 2020; Marengo et al., 2020a; Olmo et al., 2020) (WGI AR6 Table 11.14) (Seneviratne et al., 2021). A higher observed frequency of extratropical cyclones in the region has been detected (Parise et al., 2009; Reboita et al., 2018) with three cyclogenetic foci: South-southeast Brazil, extreme south of Brazil and Uruguay, and southeast of Argentina.

In Montevideo, mean sea-levels increased over the past 20 years, reaching 11 cm from 1902 to 2016, and a recent accelerating trend has been observed (Gutiérrez et al., 2016b). A value of water-level rise and its acceleration for Buenos Aires was calculated from a record of annual mean water levels obtained from hourly levels (1905–2003). Annual mean water level showed a trend of $+1.7 \pm 0.05$ mm yr^{-1}, and an acceleration of $+0.019 \pm 0.005$ mm yr^{-2} (D'Onofrio et al., 2008).

Increasing trends in mean air temperature and extreme heat, and decreasing cold spells are projected (*high confidence*) (WGI AR6 Table 12.6Ranasinghe et al., 2021). The increase in the frequency of warm nights is larger than that projected for warm days consistent with observed past changes that have been related with changes in cloud cover that affect differently daytime temperatures as compared to night time temperatures (López-Franca et al., 2016; Menéndez et al., 2016; Feron et al., 2019).

Increases in mean precipitation (*high confidence*), pluvial floods and river floods are projected (*medium confidence*) (Nunes et al., 2018) (WGI AR6 Table 12.6) (Ranasinghe et al., 2021). Droughts in the La Plata Basin will be more frequent in the medium-term (2011-2040) and the distant future (2071-2100) (with respect to the 1979-2008 period), but also shorter and more severe, for the more extreme emission scenario (RCP8.5) (*low confidence*) (Carril et al., 2016).

Negative trend in the annual number of cyclone events in the long-term future of 3.6 to 6.5% (2070-2098) are projected, that showed an increase of 3 to 11% (2080-2100 for the A1B scenario) (Grieger et al., 2014; Reboita et al., 2018). All coastal and oceanic climate impact drivers (relative sea level, coastal flood and erosion, marine heatwaves and ocean aridity) are expected to increase by mid-century in the RCP8.5 scenario (*high confidence*) (WGI AR6 Table 12.6, Ranasinghe et al., 2021).

12.3.6.2 Exposure

Higher temperatures and rising sea levels, changes in rainfall patterns, increased frequency and intensity of extreme weather events, could generate risks to the energy and the infrastructure sectors, and to the mining and metals network. In the Plata basin, urban floods have become more frequent, causing infrastructure damage and sometimes substantial mortality (*high confidence*) (Barros et al., 2015; Zambrano et al., 2017; Nagy et al., 2019; Mettler-Grove, 2020; Morales-Yokobori, 2021; Oyedotun and Ally, 2021). A large increase in landslides and flash floods is also predicted for the Brazilian portion of SES, where they are responsible for the majority of the deaths related to natural disasters in the country (*high confidence*) (Debortoli et al., 2017; Haque et al., 2019; Saito et al., 2019; Marengo et al., 2020d; da Fonseca Aguiar and Cataldi, 2021). Due to uncontrolled urban growth, 21.5 million people living in the large Brazilian cities of São Paulo, Rio de Janeiro and Belo Horizonte (estimate from IBGE (2019)) are expected to be exposed to water scarcity, despite great water availability in the region (*medium evidence, medium agreement*) (Marengo et al., 2017; Lima and Magaña Rueda, 2018; Marengo et al., 2020b).

The expected increase in temperature also exposes the population in large cities to extreme heat. Urban heat islands are already a reality in large cities in the region, such as Buenos Aires (*high confidence*) (Wong et al., 2013; Sarricolea and Meseguer-Ruiz, 2019; Wu et al., 2019; Mettler-Grove, 2020), Rio de Janeiro (*high* *confidence*) (Ceccherini et al., 2016; Neiva et al., 2017; Geirinhas et al., 2018; Peres et al., 2018; Sarricolea and Meseguer-Ruiz, 2019; Wu et al., 2019; de Farias et al., 2021) and São Paulo (*high confidence*) (Mishra et al., 2015; Barros and Lombardo, 2016; Ceccherini et al., 2016; Vemado and Pereira Filho, 2016; de Azevedo et al., 2018; Lima and Magaña Rueda, 2018; Ferreira and Duarte, 2019; Lapola et al., 2019a; Sarricolea and Meseguer-Ruiz, 2019; Wu et al., 2019), with reported impact on human health in the latter (*medium confidence: medium evidence, medium agreement*) (e.g., Araujo et al. (2015); Son et al. (2016); Diniz et al. (2020)). These cities alone represent 22 million people exposed to increased heat (estimate from IBGE (2019) and from INDEC (2010)).

The sub-region presents a high frequency of occurrence of intense severe convection events (Section 12.3.6.1). Because of this situation, strong winds from the south or southeast and high water levels affect the whole Argentine coast, as well as the Rio de la Plata shores, Uruguay, and southern Brazil (Isla and Schnack, 2009). The coast of the Plata River is subject to flooding when there are strong winds from the southeast (sudestadas). As sea level rises as a result of global climate change, storm surge floods will become more frequent in this densely populated area, particularly in low-lying areas (*high confidence*) (Figure 12.8; D'Onofrio et al., 2008; Nagy et al., 2014a; Santamaria-Aguilar et al., 2017; Nagy et al., 2019 impacts and adaptation in Central and South America coastal areas; Cerón et al., 2021) .

The region's natural systems are also exposed to climate change. SES region houses two important biodiversity hotspots, with high levels of species endemism: the Cerrado and the Atlantic Forest, where about 72% of Brazil's threatened species can be found (PBMC, 2014).

12.3.6.3 Vulnerability

The Rio de la Plata basing and the city of Buenos Aires are highly vulnerable to recurring floods, and the increasing number of newcomers to the area reduce the collective cultural adaptation developed by older neighbours (*high confidence*) (Barros, 2006; Nagy et al., 2019; Mettler-Grove, 2020; Morales-Yokobori, 2021; Oyedotun and Ally, 2021). Extreme events, including storm surges and coastal inundation/flooding caused injuries and economic/environmental losses on the urbanized coastline of Southern Brazil (States of Sao Paulo and Santa Catarina) (*high confidence*) (Muehe, 2010; Khalid et al., 2020; Ohz et al., 2020; de Souza and Ramos da Silva, 2021; Quadrado et al., 2021; Silva de Souza et al., 2021).

Cities like Rio de Janeiro and São Paulo are overpopulated, where most people live in poor conditions of inadequate housing and sanitation, such as slums, with little and no trees and high temperatures. These people have low access to sanitation, public health and residential cooling and are vulnerable to the effects of heat islands on human comfort and health (Figure 12.7). These include cardiopulmonary and vector-borne diseases, and even death (*medium confidence: medium evidence, medium agreement*) (Araujo et al., 2015; Mishra et al., 2015; Geirinhas et al., 2018; Peres et al., 2018). Heat stress is known to worsen cardiovascular, diabetic and respiratory conditions (Lapola et al., 2019a). As an effect of Heat islands, these people are also vulnerable to injuries and casualties due to increased thunderstorms, causing economic losses and other social problems (Vemado and Pereira Filho, 2016).

12.3.6.4 Impacts

Despite the observed increase in rainfall amount in the region, between 2014 and 2016 Brazil endured a water crisis that affected the population and economy of major capital cities in the SES region Brazil (Blunden and Arndt, 2014; Nobre et al., 2016a). Extremely long dry spells have become more frequent in southeast of Brazil, affecting 40 million people and the economies in cities such as Rio de Janeiro, São Paulo and Belo Horizonte, which are the industrial pole of the country (*medium confidence: medium evidence, medium agreement*) (PBMC, 2014; Nobre et al., 2016a; Cunningham et al., 2017; Marengo et al., 2017; Lima and Magaña Rueda, 2018; Marengo et al., 2020b). It also impacted agriculture, affecting food supply and rural livelihoods, especially in Minas Gerais (Nehren et al., 2019). Agricultural prices increased by 30% in some cases and harvest yields of sugar cane, coffee and fruits suffered a reduction of 15–40% in the region. The number of fires increased by 150%, and energy prices increased by 20–25%, as most electricity from hydroelectric power (Nobre et al., 2016a). In Argentina, projected changes in hydrology of Andean rivers associated to glacier retreat are predicted to have negative impacts on the region's fruit production (*low evidence, medium agreement*) (Barros et al., 2015).

Heat islands affect ecosystems by increasing the energy consumption for cooling, the concentration of pollutants and the incidence of fires (*high confidence*) (Wong et al., 2013; Akbari and Kolokotsa, 2016; Singh et al., 2020b; Ulpiani, 2021). It also affects human health, as well increasing the incidence of respiratory, cardiovascular diseases (*medium confidence: medium evidence, medium agreement*) (Araujo et al., 2015; Barros and Lombardo, 2016; de Azevedo et al., 2018; Geirinhas et al., 2018).

Warming temperatures have been implicated in the emergence of dengue in temperate latitudes increasing populations of *Aedes aegypti* (*high confidence*) (Natiello et al., 2008; Robert et al., 2019; Estallo et al., 2020; Robert et al., 2020; López et al., 2021) (Table 12.1), and field studies have shown the role of local climate in vector activity (Benitez et al., 2021). Figure 12.5 shows the modelled transmission suitability for dengue for two climate change scenarios. Future increase in the number of months suited for transmission of dengue is highest in SES (see SM12.8 for additional information). There is additional evidence of the spread of arbovirus transmission into southern temperate latitudes (Basso et al., 2017), however a longer historical time series is needed to understand climate-disease interactions, given the relatively recent emergence in this region.

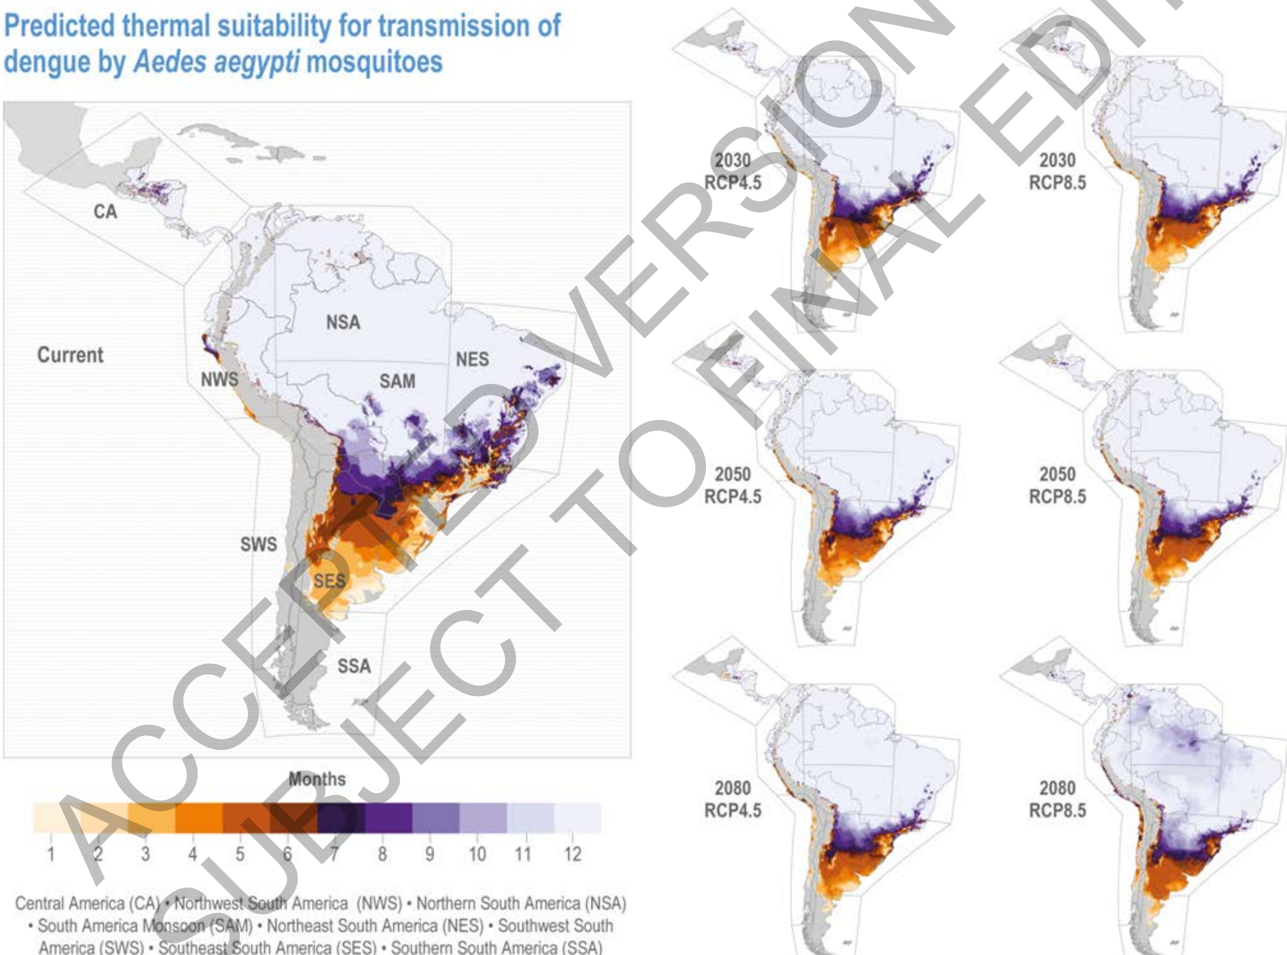

Figure 12.5: Predicted thermal suitability for transmission of dengue by *Aedes aegypti* mosquitoes, mapped as the number of months of the year suitable under baseline or current conditions (2015), and in 2030, 2050, 2080 under two representative concentration pathways, RCP4.5 and RCP8.5. Adapted from Ryan et al. (2019). See SM12.8 for additional data on population at risk for dengue and Zika in the subregions and methodological details.

Sea-level rise impacted the port complex in Santa Catarina, which during the last six years interrupted its activities 76 times due to strong winds or big waves with estimated losses varying between USD 25,000 and USD 50,000 for each 24 idle hours (Ohz et al., 2020). Historically, extratropical cyclones associated with frontal systems cause storm surges in Santos city. Although there are no fatality records, these events cause several socio-economic losses, especially in vulnerable regions including the Port of Santos, the largest port in Latin America (São Paulo). According to 88-year time span (1928-2016), the frequency of storm surge events were three times more frequent in the last 17 years (2000-2016), than in the previous period of 71 years (1928-1999) (Souza et al., 2019).

There are many projected impacts of climate change on natural systems. The impacts of sea-level rise are habitat destruction and the invasion of exotic species, affecting biodiversity and the provision of ecosystem services (Figure 12.8; Nagy et al., 2019) ().

SES is a global priority for terrestrial biodiversity conservation, housing two important biodiversity hotspots—the Atlantic Forest and Cerrado—which are among the World's most studied biodiversity-rich spots in terms of climate change impact on biodiversity, especially for terrestrial vertebrates (Cross-Chapter Paper 1.2.2; Manes et al., 2021) . An increasing number of studies show that the Atlantic Forest and Cerrado are at risk of biodiversity loss, largely due to projected reduction of species' geographic distributions in many different taxa (e.g., Loyola et al. (2012); Ferro et al. (2014); Loyola et al. (2014); Hoffmann et al. (2015); Martins et al. (2015); Aguiar et al. (2016b); Vale et al. (2018); Borges et al. (2019); Braz et al. (2019); Vale et al. (2021)). Cerrado savannas are projected to be the hotspot most negatively impacted by climate change within South America, mostly though range contraction of plant species (*very high confidence*), while the Atlantic Forest is projected to be highly impacted especially though the contraction of the distribution of endemic species (*very likely*) (Cross-Chapter Paper 1.2.2; Figure 12.10; Manes et al., 2021) . Reductions in species' distribution are also projected in the La Plata Basin for subtropical amphibians (Schivo et al., 2019) and the river tiger (*Salminus brasiliensis*), a keystone fish of economic value (Ruaro et al., 2019). Farming of mussels and oysters in the region is predicted to be negatively impacted by climate change, particularly sea-level rise, and ocean warming and acidification (Gasalla et al., 2017). Some more localized habitats are also at risk of losing area due to climate change, such as the meadows of northwest Patagonia (Crego et al., 2014) and mangroves of southern Brazil (Godoy and Lacerda, 2015). Predicted changes in global climate along with agricultural expansion will strongly affect South American wetlands, which comprise around 20% of the continent and bring many benefits, such as biodiversity conservation and water availability (Junk, 2013).

12.3.7 Southwest South America (SWS) Sub-region

12.3.7.1 Hazards

Significant increases in the intensity and frequency of hot extremes and significant decreases in the intensity and frequency of cold extremes have *likely* been observed for the region (Skansi et al., 2013; Ceccherini et al., 2016; Meseguer-Ruiz et al., 2018; Vicente-Serrano et al., 2018; Dereczynski et al., 2020; Dunn et al., 2020; Olmo et al., 2020) (WGI AR6 Table 11.13) (Seneviratne et al., 2021). In particular, a significant increment in the duration and frequency of heatwaves mainly in central Chile from 1961 to 2016 has been observed (Piticar, 2018).

A robust drying trend for Chile (30ºS–48°S) has been recorded (*medium confidence*) (Saurral et al., 2017; Boisier et al., 2018). However, inconsistent trends over the region in the magnitude of precipitation extremes with both decreases and increases (Chou et al., 2014; Giorgi et al., 2014; Heidinger et al., 2018; Meseguer-Ruiz et al., 2018) (WGI AR6 Table 11.14) (Seneviratne et al., 2021) have been observed (*low confidence*). The glacier equilibrium line altitude has presented an overall increase over central Chilean Andes (Barria et al., 2019).

For central Chile, a significant increase (5% to 20% in the last 60 years) in wave heights in the sea has been observed (Martínez et al., 2018). From 1982 to 2016, sea level at central Chile have increased 5 mm yr^{-1}, where El Niño events of 1982-1983 and 1997-1998 caused an extreme increase of 15 to 20 cm in the mean sea level (Campos-Caba, 2016; Martínez et al., 2018).

From 1946 to 2017, the number of fires and areas burned have increased significantly in Chile (*high confidence*) (González et al., 2011; Jolly et al., 2015; Úbeda and Sarricolea, 2016; de la Barrera et al., 2018; Urrutia-Jalabert et al., 2018). Fires are attributed to changes in the temperatures regimes (González et al., 2011; de la Barrera et al., 2018; Gómez-González et al., 2018) and precipitation regimes (*medium confidence*) (Gómez-González et al., 2018; Urrutia-Jalabert et al., 2018).

The glaciers of the Southern Andes (including the SWS and SSA regions) show the highest glacier mass loss rates worldwide (*high confidence*) contributing to sea level rise (Jacob et al., 2012; Gardner et al., 2013; Dussaillant et al., 2018; Braun et al., 2019; Zemp et al., 2019). Since 1985, the glacier area loss in the sub-region is in a range of 20 up to 60% (Braun et al., 2019; Reinthaler et al., 2019b).

Four sets of downscaling simulations based on the Eta Regional Climate Model forced by two global climate models (Chou et al., 2014) projected warmer conditions (more than 1°C) for all the sub-region by 2050 under the RCP4.5 scenario (*medium confidence*). Extremely warm December-January-February days as well as the number of heatwaves per season are expected to increase by 5–10 times in the northern Chile (Feron et al., 2019)*, likely* increasing in the intensity and frequency of hot extremes over all the region (WGI AR6 Table 11.13) (Seneviratne et al., 2021). Drier conditions (*medium confidence*), by mean of the decrease of total annual and extreme precipitations, are expected to increase for Southern Chile but inconsistent changes in the sub-region (*low confidence*) (Chou et al., 2014) (WGI AR6 Table 11.14) (Seneviratne et al., 2021) with *high confidence* on increase of fire weather and decrease of permafrost and snow extent (WGI AR6 Table 12.6, Ranasinghe et al., 2021).

Regional sea-level change for the region predicted by 2100 show that total mean SLR along the coast will lie between 34 cm and 52 cm for the RCP4.5 scenario, and between 46 cm and 74 cm for the RCP8.5 scenario with *high confidence* (Albrecht and Shaffer, 2016; WGI AR6 Table 12.6, Ranasinghe et al., 2021).

12.3.7.2 Exposure

There is *high confidence* that age and socio-economic status are key factors determining health exposure and quality of life in SWS where low-income areas show an insufficient number of public spaces to provide acceptable environmental quality in comparison with the high-income areas (Romero-Lankao et al., 2013; Fernández and Wu, 2016; Paz et al., 2016; Hystad et al., 2019; Smith and Henríquez, 2019; Jaime et al., 2020; Pino-Cortés et al., 2020).

Profound social inequalities, urban expansion and the inadequate city planning (e.g., drainage network) increase exposure to flooding events and landslides (*high confidence*) (Müller and Höfer, 2014; Rojas et al., 2017; Lara et al., 2018), heat hazards such as heatwaves (*high confidence*) (Welz et al., 2014; Qin et al., 2015; Inostroza et al., 2016; Welz and Krellenberg, 2016; Krellenberg and Welz, 2017), and the loss and fragmentation of green infrastructure (Hernández-Moreno and Reyes-Paecke, 2018). SWS cities show the highest levels of air pollution of CSA (*medium confidence: medium evidence*, *high agreement*) (Pino et al., 2015; Huneeus et al., 2020; González-Rojas et al., 2021), where the state air quality alerts have limited effect on protective health behaviours, being the public perception about air pollution highly dissimilar among the population (Boso et al., 2019). In particular, human communities living in coastal cities show a negative safety perception about the performance of the infrastructure and coastal defences to flood events (*low confidence*) (González and Holtmann-Ahumada, 2017; Igualt et al., 2019).

Although climate change is critically important for the current and future status of mining activity in SWS (Odell et al., 2018), and SWS areas subjected to mining activities are highly exposed to water risk (Northey et al., 2017), to date, there is *low evidence* of climate change impacting mining activities (Corzo and Gamboa, 2018; Odell et al., 2018).

12.3.7.3 Vulnerability

Rapid changes in temperature and precipitation regimes make terrestrial ecosystems highly vulnerable to climate change (*high confidence*) (Salas et al., 2016; Fuentes-Castillo et al., 2020) (Figure 12.7). Terrestrial ecosystems dominated by exotic species (e.g., pine) with lower landscape heterogeneity, degraded soils and close to settlements and roads are highly vulnerable to wildfires in comparison to forests dominated by native trees (*high confidence*) (Altamirano et al., 2013; Castillo-Soto et al., 2013; Cóbar-Carranza et al., 2014; Salas et al., 2016; Bañales-Seguel et al., 2018; Gómez-González et al., 2018; Sarricolea et al., 2020). Changes in the land use, artificial forestation, deforestation, agricultural abandonment and urbanization have provoked a permanent degradation of old-growth forest putting at risk the biodiversity, recreation and ecotourism (*medium confidence: medium evidence, high agreement*) (Rojas et al., 2013; Nahuelhual et al., 2014). Marine coastal ecosystems such as dunes, sandy beaches and wetlands show a high deterioration decreasing the ability to mitigate extreme events (*medium confidence: low evidence*, *high agreement*) (González and Holtmann-Ahumada, 2017; Ministerio de Medio Ambiente de Chile, 2019).

Water sector shows a very high vulnerability (*high confidence*) (Figure 12.7) mainly due the weak water governance focused on market aspects (e.g., inter-sectoral water transactions, setting rates, granting concessions, waiving the water right) (*high confidence*) (Hurlbert and Diaz, 2013; Valdés-Pineda et al., 2014; Barría et al., 2019; Hurlbert and Gupta, 2019; Muñoz et al., 2020a; Urquiza and Billi, 2020b). Potable water and adequate sanitization is available in SWS; however, water availability along Chile is unevenly distributed in rural communities (*high confidence*) (Valdés-Pineda et al., 2014; Nelson-Nuñez et al., 2019). Spatial differences on water availability are enhanced by the strong population growth, economic development, mining activities, and the high dependence of agriculture to irrigation (*high confidence*) (Stathatou et al., 2016; Northey et al., 2017; Fercovic et al., 2019). Droughts in SWS are a major threat to water security (*high confidence*) (Aitken et al., 2016; Núñez et al., 2017) as river streamflow are highly dependent on the inter-annual to decadal climate conditions, snow melting processes, rainfall events (Boisier et al., 2016), and impacted by land uses and changes in irrigated agriculture (*medium confidence: medium evidence, high agreement*) (Vicuña et al., 2013; Fuentes et al., 2021).

Energy and water needs of large-scale mining activities make this socio economic sector particularly vulnerable to climate change; additionally, the relative lack of power of resource-poor communities living in areas where such mining is making claims on water and energy resources renders these communities even more vulnerable (Odell et al., 2018). Given new conditions generated by changes in a growing demand and climate change, mining industries will need to increase resilience to extreme events; additionally, the declining concentrations of mineral of interest in the raw material require greater energy input for extraction and processing and new methods to avoid associated emissions are required (Hodgkinson and Smith, 2018).

Urban and agriculture sectors are vulnerable to climate change (*medium confidence: medium evidence, high agreement*) (Figure 12.7) increasing problems and demand for water (*high confidence*) (Monsalves-Gavilán et al., 2013; Meza et al., 2014; Fercovic et al., 2019). Important health problems (e.g., pathogenic infections, changes in vector-borne diseases, mortality by heat, lower neurobehavioral performance, among others) have been associated with agriculture, mining and thermal power production activities along SWS (*high confidence*) (Muñoz-Zanzi et al., 2014; Valdés-Pineda et al., 2014; Pino et al., 2015; Cortés, 2016; Berasaluce et al., 2019; Muñoz et al., 2019a; Ramírez-Santana et al., 2020).

The large-scale agricultural growth has increased the vulnerability to climate change by favouring the detriment of traditional agriculture, the homogenization of the biophysical landscape and the replacement of traditional crops and native forests with exotic species like pines and eucalyptus (*high confidence*) (Torres et al., 2015) where farmers' climate change perception is highly dependent on the education level and the access to meteorological information (*low confidence*) (Roco et al., 2015). Agricultural systems owned by Indigenous Peoples (i.e., Mapuche, Quechua and Aymara farmers) seem to present lower vulnerability to drought and higher response capacity than non-indigenous farmers thanks to the use of the traditional knowledge of specific management techniques and the tendency to conserve species or varieties of crops tolerant to water scarcity (*low confidence*) (Montalba et al., 2015; Saylor et al., 2017; Meldrum et al., 2018). Fishery and aquaculture-related livelihoods are vulnerable to climate and non-climate drivers (*medium confidence: medium evidence, high agreement)* such as sea surface warming and precipitation reduction (Handisyde et al., 2017; Soto et al., 2019; González et al., 2021), changes in upwelling intensity (*low confidence*) (Oyarzún and Brierley, 2019; Ramajo et al., 2020), eutrophication and harmful algal bloom (HAB) events (Almanza et al., 2019), the lack of observational elements and data management (Garçon et al., 2019), and events such as earthquakes and tsunamis (Marín, 2019).

Chile has experienced an accelerated economic growth which has reduced poverty, however important geographical, economic and educational inequalities are still present (Repetto, 2016). Chilean healthcare system has become more equitable and responsive to the population necessities (e.g., Health reform AUGE program); however, the high relative inequalities in terms of income (OECD, 2018), education level, and the rural–urban factor are determinants of the quality of care, the health system barriers, and the health differential access (*high confidence*) (Frenz et al., 2014). Exposure and vulnerability to psychosocial risks in SWS shows significant inequalities to natural disasters such as earthquakes according to socio-economic, geographic and gender factors (*high confidence*) (Labra, 2002; Vitriol et al., 2014; Quijada et al., 2018) which are increased by the absence of local planning and drills and the lack of coordination (Vitriol et al., 2014). Indigenous Peoples have the highest levels of vulnerability in Chile in terms of income, basic needs, and access to services to climate change (*low confidence*) (Parraguez-Vergara et al., 2016).

12.3.7.4 Impacts

Increasing temperatures in SWS have impacted temperate forests (*high confidence*) (Peña et al., 2014; Urrutia-Jalabert et al., 2015; Camarero and Fajardo, 2017; Fontúrbel et al., 2018; Venegas-González et al., 2018b; Peña-Guerrero et al., 2020). Increasing temperatures and decreasing precipitations have increased the impacts of wildfires on terrestrial ecosystems (*high confidence*) (Boisier et al., 2016; Díaz-Hormazábal and González, 2016; Martinez-Harms et al., 2017; de la Barrera et al., 2018; Gómez-González et al., 2018; Urrutia et al., 2018; Bowman et al., 2019), creating conditions for future landslides and floods (de la Barrera et al., 2018).

Future projections show important changes in the productivity, structure and biogeochemical cycles in SWS temperate and rainforests (*medium confidence: medium evidence, high agreement*) (Gutiérrez et al., 2014; Correa-Araneda et al., 2020), and their fauna (*low confidence*) (Glade et al., 2016; Bourke et al., 2018). The "Chilean Winter Rainfall-Valdivian Forests" is a biodiversity-rich spot (Manes et al., 2021) (Cross-Chapter Paper 1.2.2) projected to suffer habitat change, with loss of vegetation cover in the future due to climate change (*medium confidence: medium evidence, high agreement*) (Jantz et al., 2015; Mantyka-Pringle et al., 2015). Species are projected to suffer changes in their distribution, including decrease in climatic refugia for vertebrates (*low confidence*) (Cuyckens et al., 2015; Warren et al., 2018).

Increasing temperatures have enlarged the number and area extent of glacier lakes in Central Andes, Northern Patagonia and Southern Patagonia (*high confidence*) (Wilson et al., 2018), while decreased rainfall and rapid glacier melting have provoked changes in the environmental, biogeochemical and biological properties of the central-southern and Andes Chilean lakes (*low confidence*) (Pizarro et al., 2016).

Increasing glacier lake outburst floods (GLOF), ice and rock avalanches, debris flows, and lahars from ice-capped volcanoes have been observed in SWS (Iribarren Anacona et al., 2015; Jacquet et al., 2017; Reinthaler et al., 2019b). There is *low evidence* about the effects of warming and degrading permafrost on slope instability and landslides in these regions (Iribarren Anacona et al., 2015).

Increasing temperatures, decreasing precipitation regimes, and an unprecedented long-term drought have decreased the annual average rivers streamflow that supply SWS megacities such as Santiago (*high confidence*) (Meza et al., 2014; Muñoz et al., 2020a), with important and negative effects over the water quality (Bocchiola et al., 2018; Yevenes et al., 2018) threatening irrigated agriculture activities (*medium confidence: medium evidence, high agreement*) (Yevenes et al., 2018; Oertel et al., 2020; Peña-Guerrero et al., 2020). Large reductions in the groundwater availability of the SWS region (Meza et al., 2014) and a sustained decreasing of the mean annual flows (Ragettli et al., 2016; Bocchiola et al., 2018), especially during the snowmelt season (Vargas et al., 2013) have been observed in SWS. Drought has affected wetlands (*low confidence*) (Zhao et al., 2016; Domic et al., 2018), and desert ecosystems (*medium confidence: medium evidence, high agreement)* (Acosta-Jamett et al., 2016; Neilson et al., 2017; Díaz et al., 2019).

There is *low evidence* about shoreline retreat attributed to climate change (Martínez et al., 2018; Ministerio de Medio Ambiente de Chile, 2019) although increasing wind intensity along the central Chilean coast has caused important damages in the coastal infrastructure and buildings (Winckler et al., 2017) and changes of seawater properties and processes (*low confidence*) (Schneider et al., 2017; Aguirre et al., 2018). Ocean and coastal ecosystems in SWS are sensitive to upwelling intensity which affect the abundance, diversity, physiology and survivorship of coastal species (*high confidence*) (Anabalón et al., 2016; Jacob et al., 2018; Ramajo et al., 2020) (Figure 12.8). Increasing radiation and temperatures, and reduced precipitations in conjunction with increased nutrient load have increased HAB events producing massive fauna mortalities (*high confidence*) (León-Muñoz et al., 2018; IPCC, 2019b, SPM A8.2 and B8.3; Quiñones et al., 2019; Soto et al., 2019; Armijo et al., 2020). Multiple resources subjected to fisheries and aquaculture are highly vulnerable to storms, alluvial disasters, ocean warming, ocean acidification, increasing ENSO extreme events, and lower oxygen availability (*high confidence*) (Figure 12.8; García-Reyes et al., 2015; Silva et al., 2015; Duarte et al., 2016; Lagos et al., 2016; Navarro et al., 2016; Lardies et al., 2017; Duarte et al., 2018; IPCC, 2019b; Mellado et al., 2019; Ramajo et al., 2019; Silva et al., 2019a; Bertrand et al., 2020). Ocean and coastal ecosystems, especially the EEZ will be highly impacted by climate change in the near and long-term (*high confidence*) (Figure 12.8; Table SM12.3; Silva et al., 2015; Silva et al., 2019a).

Changes in the temperature and drought have impacted crops significantly (*medium confidence: medium evidence, high agreement*) (Ray et al., 2015; Zambrano et al., 2016; Lesjak and Calderini, 2017; Ferrero et al., 2018; Piticar, 2018; Haddad et al., 2019; Zúñiga et al., 2021). Table 12.4 shows the changes in crop growth duration, which affect the yields. Higher negative numbers then indicate yield reduction for the crop. Increasing temperatures and decreasing precipitation are expected to impact the agriculture sector (i.e., fruits crops, and forests) across the entire sub-region with the largest impacts in the northern and central zone (*high confidence*) (Mera et al., 2015; Zhang et al., 2015; Silva et al., 2016; Lizana et al., 2017; Reyer et al., 2017; Toro-Mujica et al., 2017; Beyá-Marshall et al., 2018; Lobos et al., 2018; O'Leary et al., 2018; Aggarwal et al., 2019; Ávila-Valdés et al., 2020; Fernandez et al., 2020; Melo and Foster, 2021). Observed impacts and future projections warn that increasing temperatures and decreasing precipitation will largely impact on water demand by agricultural sectors (*high confidence*) (Novoa et al., 2019; Peña-Guerrero et al., 2020; Webb et al., 2020). Extreme climate events have provoked that Indigenous Peoples (e.g., Mapuche, Uru and Aymara) suffer scarcity of water, reduction of agricultural production, and a displacement of their traditional knowledge and practices (*medium confidence: low evidence, high agreement*) (Parraguez-Vergara et al., 2016; Meldrum et al., 2018; Perreault, 2020).

Table 12.4: Average percentage change in crop growth duration for the period 2015-19. Crop growth duration refers to the time taken in a year for crops to accumulate the reference period (1981-2010) average growing season Accumulated Temperature Total (ATT). As temperatures rise, the ATT is reached earlier (higher negative changes), the crop matures too quickly, and thus yields are lower. "No data" means no data is available for the growth of that crop, in the specified region. NP means that the crop is not present in significant areas in that region. Data derived from Romanello et al. (2021).

Region	Winter wheat	Spring wheat	Rice	Maize	Soybean
Central America (CA)	-4.8%	No data	-1.9%	-5.0%	-4.7%
Northwest South America (NWS)	-3.8%	-5.2%	-5.2%	-5.6%	-3.1%
Northern South America (NSA)	NP	NP	-0.7%	-3.1%	0.0%
South America Monsoon (SAM)	-5.3%	-0.7%	-1.4%	-2.9%	-1.5%
Northeast South America (NES)	-1.0%	-1.3%	-0.7%	-3.5%	-2.6%
Southeast South America (SES)	-2.3%	-3.5%	-2.3%	-2.4%	-2.7%
Southwest South America (SWS)	-2.3%	-5.2%	-10.0%	-5.2%	No data
Southern South America (SSA)	-0.8%	-6.5%	No data	-1.6%	No data

SWS cities have been largely impacted by wildfires, water scarcity and landslides affecting highways and local roads, as well as, potable water supply (Sepúlveda et al., 2015; Araya-Muñoz et al., 2016). Increasing temperature and heat extreme events in cities have increased the demand for water, the damage of urban infrastructure (Monsalves-Gavilán et al., 2013), and accelerated the ageing and the death of trees (*high confidence*) (Moser-Reischl et al., 2019). Increasing temperature will modify the energy demand in cities in northern and central Chile (Rouault et al., 2019).

Increasing temperature, heat extreme events and air pollution in SWS have significantly impacted the population health (cardiac complications, heat stroke, and respiratory diseases) (*high confidence*) (Table 12.2; Leiva G et al., 2013; Monsalves-Gavilán et al., 2013; Pino et al., 2015; Herrera et al., 2016; Henríquez and Urrea, 2017; Ugarte-Avilés et al., 2017; de la Barrera et al., 2018; Johns et al., 2018; Bowman et al., 2019; González et al., 2019; Matus C and Oyarzún G, 2019; Sánchez et al., 2019; Terrazas et al., 2019; Cakmak et al., 2021; Zenteno et al., 2021).There is *low confidence* about area changes of Chagas disease (Tapia-Garay et al., 2018; Garrido et al., 2019), and transmission rates in the future (Ayala et al., 2019).

12.3.8 Southern South America (SSA) Sub-region

12.3.8.1 Hazards

There were inconsistent trends and insufficient data coverage about extreme temperatures and precipitation (*low confidence*) but with *medium confidence* an increase in the frequency of meteorological droughts was observed (Dereczynski et al., 2020; Dunn et al., 2020; WGI AR6 Tables 11.13, 11.14, 11.15, Seneviratne et al., 2021; WGI AR6 Table 12.3, Ranasinghe et al., 2021). An increase in precipitation in Trelew, no change for Comodoro Rivadavia, both stations located at Eastern Patagonia, and negative trends in austral summer rainfall in southern Andes were observed (Vera and Díaz, 2015; Saurral et al., 2017). Chile's wildfires in Patagonia (fire frequency and intensity) have grown at an alarming rate (Úbeda and Sarricolea, 2016). Decreasing rainfall pattern in Punta Arenas is closely associated with the variability at inter-annual to inter-decadal time scales of the main forcing system for climate in Patagonia. Snow Cover Extension (SCE) and Snow Cover Duration decreased by an average of ~13 ± 2% and 43 ± 20 days respectively from 2000 to 2016, due to warming rather than drying (Rasmussen et al., 2007). In particular, the analysis of spatial pattern of SCE indicates a slightly greater reduction on the eastern side (~14 ± 2%) of the Andes Cordillera compared to the western side (~12 ± 3%). The longest time series of glacier mass balance data in the Southern Hemisphere, the Echaurren Norte Glacier, lost 65% of its original area in the period 1955–2015 and disaggregated into two ice bodies in the late 1990s (Malmros et al., 2018; Pérez et al., 2018).

Mean temperatures in the SSA sub-region are projected to continue to rise up to +2.5°C in 2080 with respect to the present climatology (Kreps et al., 2012). A rise in temperature means that the isotherm of 0°C will move up the mountains leaving less surface for accumulation of snow (Barros et al., 2015).

An increase in the intensity and frequency of hot extremes and a decrease in the intensity and frequency of cold extremes is *likely* projected (WGI AR6 Table 11.13, Seneviratne et al., 2021); CMIP6 models project an increase in the intensity and frequency of heavy precipitation (*medium confidence*).

It is expected that an increase in the intensity of heavy precipitation, droughts and fire weather will intensify through the 21st century in SSA but mean wind will decrease (*medium confidence*) (Kitoh et al., 2011; WGI AR6 Tables 11.14 and Table 11.15, Seneviratne et al., 2021). The probability of having extended droughts, such as the recently experienced mega-drought (2010-2015), increases to up to 5 events/100 yr (Bozkurt et al., 2017). Snow, glaciers, permafrost and ice sheets will decrease with *high confidence* (WGI AR6 Table 12.6, Ranasinghe et al., 2021). The observed area and the elevation changes indicate that the Echaurren Norte Glacier may disappear in the coming years if negative mass balance rates prevail (*medium confidence*) (Farías-Barahona et al., 2019).

12.3.8.2 Exposure

Grasslands make a significant contribution to food security in Patagonia through providing part of the feed requirements of ruminants used for meat, wool and milk production. There is a lack of information regarding the combined effect of climate change and overgrazing and the consequences for pastoral livelihoods that depend on rangelands. Temperature and the amount and seasonal distribution of precipitation were important controls of vegetation structure in Patagonian rangelands (Gaitán et al., 2014). They found that over two-thirds of the total effect of precipitation on above-ground net primary production (ANPP) was direct, and the other third was indirect (via the effects of precipitation on vegetation structure). Thus, if evapotranspiration and drought stress increase as temperature increases and rainfall decrease in water-limited ecosystems, it would be expected a greater exposure of ranchers due to a reduction of stocking rate and therefore families' income (*medium confidence*). The number of farmers (mainly family enterprises) exposed to climatic hazards (drought) is approximately 70–80 thousand that have 14–15 million sheep in Argentina (Peri et al., 2021).

Argentinian Patagonia main cities have developed as the result of oil and gas extraction, which demand massive quantities of water due to fracking and drilling techniques. Vaca Muerta is the major region in South America where those techniques are used to extract oil and gas, and this will lead to an exacerbation of current water scarcity and to competition with irrigated agriculture (Rosa and D'Odorico, 2019) which in the context of drought may exacerbate socio-environmental conflicts (*medium confidence*).

12.3.8.3 Vulnerability

There are reports related to a decrease in survival, growth and higher vulnerability to drought and fire-severity for species of native forest due to climate change and wildfire (*high confidence*) (Mundo et al., 2010; Landesmann et al., 2015; Whitlock et al., 2015; Jump et al., 2017; Camarero et al., 2018; Venegas-González et al., 2018a). There is a reported coincidence between major changes in regional decline in the growth of forests with severe droughts due to climatic variations over northern Patagonia (Rodríguez-Catón et al., 2016). Once the forest decline begins, other contributing factors such as insects (e.g., defoliator outbreaks) increase the forest vulnerability or accelerate the loss of forest health of previously stressed trees (Piper et al., 2015). This region hosts unique temperate rainforests and it is particularly rich in endemic and long-lived conifer species (e.g., *Fitzroya cupressoides*), which may be vulnerable to declines in soil moisture availability (Camarero and Fajardo, 2017). Patagonia will probably be vulnerable by a decrease in precipitation regimes due to climate change, and consequently many species that rely on meadows in an arid environment will also be impacted (Crego et al., 2014). The floods triggered by strong ENSOs caused significant changes in the crop production (Isla et al., 2018).

The development of various human activities and water infrastructure are decreasing water sources, changing river basins from exoreic to endoreic and the disappearance of one lake in 2016 (Scordo et al., 2017). Numerous dams for irrigation, some also used for hydropower, have been and are planned to be built despite wind power generation potential (Silva, 2016). Oil and gas have played an important role in the rise of Neuquén-Cipolletti as Patagonia's most populous urban area, and in the growth of Comodoro Rivadavia, Punta Arenas, and Rio Grande, as well.

12.3.8.4 Impacts

The potential impact of climate change is of special concern in arid and semi-arid Patagonia, a >700,000 km^2 region of steppe-like plains in Argentina. Thus, melting snow and ice in the glaciers of Patagonia and the Andes will alter surface runoff into interior wetlands; sea level rise of between 20 and 60 cm will destroy coastal marshes; and an increase in extreme events, such as storms, floods, and droughts, will affect biodiversity in wet grasslands (*medium confidence: low evidence, high agreement*) (after Junk et al. 2013; Joyce et al. 2016). Three species of lizard from Patagonia are at risk of extinction as a result of global warming (Kubisch et al., 2016).

Patagonian ice fields in South America are the largest bodies of ice outside of Antarctica in the southern hemisphere. They are losing volume due partly to rapid changes in their outlet glaciers which end up in lakes or the oceans, becoming the largest contributors to eustatic sea level rise (SLR) in the world, per unit area (Foresta et al., 2018; Moragues et al., 2019; Zemp et al., 2019). Most calving glaciers in the Southern Patagonia ice field retreated during the last century (*high confidence*). Upsala Glacier retreat generated slope instability and a landslide movement destroyed the western edge in 2013. The Upsala Argentina Lake has become potentially unstable and may generate new landslides (Moragues et al., 2019). The climate effect on the summer stratification of piedmont lakes is another issue in relation to glacier dynamics (Isla et al., 2010).

Between 41º and 56° South latitude, the absolute glacier area loss was 5450 km^2 (19%) in the last ∼150 years, with an annual area reduction increase of 0.25% a^{-1} for the period 2005–2016 (Meier et al., 2018). The small glaciers in the north of the Northern Patagonian Ice field had over all periods the highest rates of 0.92% a^{-1}. In this sub-region, increased melting of ice is leading to changes in the structure and functioning of river ecosystems and in freshwater inputs to coastal marine ecosystems (*medium confidence: low evidence, high agreement*) (Aguayo et al., 2019). In addition, in the case of coastal areas, the importance of tides and rising sea levels in the behaviour of river floods has been demonstrated (Jalón-Rojas et al., 2018).

Suitable areas for meadows (very productive areas for livestock production) will decrease by 7.85% by 2050 given predicted changes in climate (*low confidence*) (Crego et al., 2014).

A major drought from 1998 to 1999 coincident with a very hot summer led to extensive dieback in a Nothofagus species (Suarez et al., 2004). In another dominant Nothofagus species, several periodic droughts have triggered forest decline as of the 1940s (Rodríguez-Catón et al., 2016).

Climate change impacted ocean ecosystems by reducing kelps coverage, increasing reproductive failure and chick mortality of penguins, and poleward expansion of saltmarshes in the Atlantic Patagonia. SSA houses the Patagonian Steppe Global-200 terrestrial ecoregion being a conservation priority at global scale, but with a clear lack of studies on likely future climate change impacts (Cross-Chapter Paper 1.2.2.2; Manes et al., 2021). The Patagonian Steppe may suffer pronounced expansion in invasive species' ranges under climate change (*low confidence*) (Wang et al., 2017a).

Fire has been found to promote or halt biological invasions (*medium confidence: medium evidence, high agreement*). For example, an analysis of *Pinus* spreading after wildfires in Patagonia reveals that there is a high risk of pines becoming invasive if ignition frequency increases as a result of climate change (Raffaele et al., 2016). According to Inostroza et al. (2016), the Magellan Region is one of the most fragile regions in Patagonia and despite its low population densities, it is under a silent process of anthropogenic alteration where between 53.1% and 68.1% of the area needs to be considered as influenced by human activity whom are occupying pristine ecosystems even extensive conservation designations (Inostroza et al., 2016). Fire exposure can result in several health problems for human populations; Table 12.5 shows that SSA is the region with the highest exposure to wildfire danger.

Table 12.5: Change in population-weighted exposure to very high or extremely high wildfire risk. Data derived from the Fire Danger Indices FDI produced by the Copernicus Emergency Management Service for the European Forest Fire Information System EFFIS (available at Copernicus Emergency Management Service (2021)). High and very high wildfire danger defined as FDI >= 5. Data derived from Romanello et al. (2021).

	Population-weighted mean days of exposure to extremely high and very high wildfire danger		
Subregion	**In 2001-04**	**In 2017-20**	**Change from 2001-04 to 2017-20**
Central America (CA)	30.4	26.9	-3.5
Northwest South America (NWS)	4.2	4.6	0.5
Northern South America (NSA)	19.7	21.2	1.5

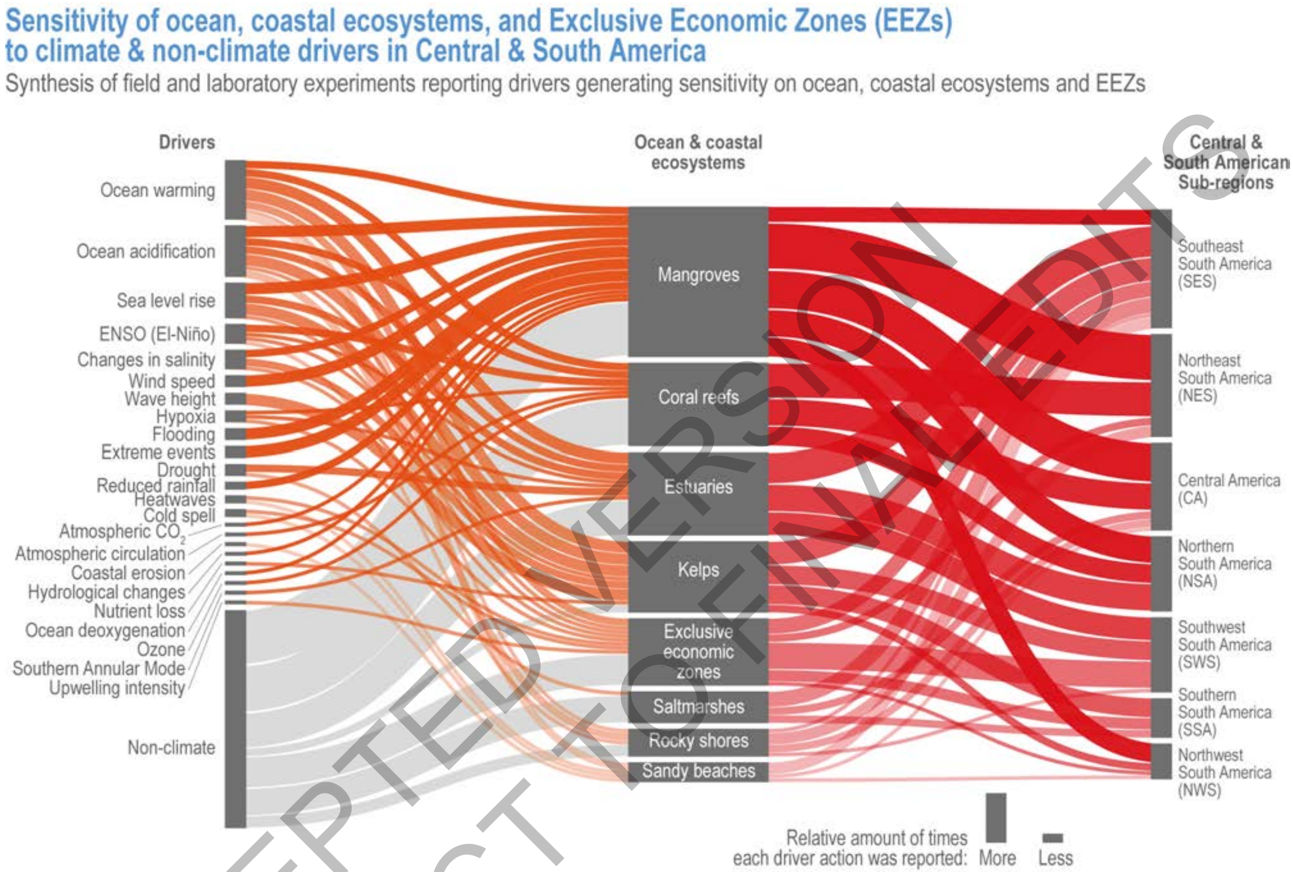

Figure 12.8: Climate and non-climate sensitivity drivers of ocean, coastal ecosystems and Exclusive Economic Zones (EEZs) of Central and South America.

12.4 Key Impacts and Risks

This section synthesizes key risks across the Central and South America CSA region. It follows the definition and concept of risk provided in AR5, distinguishing the risk components, climatic hazard, exposure and vulnerability of people and assets (IPCC, 2014). This concept is further developed in AR6, defining key risks as potentially severe risks (Section 16.5). Key risks may refer to present or future conditions, with a focus on the 21st century. Both mitigation and adaptation can moderate the extent or severity of risks. The identification and evaluation of risks imply socio-cultural values, which may vary across individuals, communities or cultures.

In line with chapter 16 of this report, this chapter uses a risk outcome perspective, i.e., the focus is on the consequences related to risks, which potentially can result from different combinations of hazards, exposure and vulnerabilities. There is limited literature with a focus on severe risks in the CSA region, and scant studies specifically and explicitly considering risk drivers such as level of warming, level of exposure, vulnerability and adaptation.

Criteria for identifying key risks for this chapter include the magnitude of the consequences, in particular the number of people potentially affected; the severity of the negative effects of the risk (e.g., lives threatened, major negative effect on livelihoods, well-being, or the economy); the importance of the affected system (e.g., for vital ecosystem services, for large population groups); the irreversibility of either the process leading to the risk or the consequences; and the potential to reduce the risk.

Several of the key risks identified for the CSA region align well with the overarching key risks assessed in AR5 (Oppenheimer et al., 2014) and later in O'Neill et al. (2017), as well as with the representative key risks assessed in Section 16.5 of this report. The identified key risks include KR1: risk of food insecurity due to frequent and/or extreme droughts; KR2: risk to life and infrastructure due to floods and landslides; KR3: risk of water insecurity; KR4: risk of severe health effects due to increasing epidemics (in particular vector-borne diseases); KR5: systemic risks of surpassing infrastructure and public service systems KR6: risk of large-scale changes and biome shifts in the Amazon; KR7: risk to coral reef ecosystems due to coral bleaching; KR8: risks to coastal socio-ecological systems due to sea level rise, storm surges and coastal erosion (Table 12.6; Figure 12.11; Table SM12.5).

Table 12.6: Synthesis of key risks identified and assessed for the Central and South America region

Consequence that would make the risk severe	**Associated changes in hazards**	**Associated changes in exposure**	**Associated changes in vulnerability**
1. Risk of food insecurity due to frequent/extreme droughts			
Substantial decrease in yield for key crops, disruption of food provision chains, reduced capacity or production of goods, reduced food security and increased malnutrition.	More frequent and/or longer drought periods. Decrease in annual rainfall, severe decrease in rainfall at onset of rainy season. Desertification of semiarid regions.	More people exposed to food insecurity due to spatially more extensive drought; high population growth rate (including rural areas) and more population dependent on agricultural goods.	Reduced capacity of farmers (especially small-scale) to adapt to changing climatic conditions. Soil degradation. Insufficient government support of adaptation measures, financial contributions, infrastructure, insurance, and research efforts. Inefficient water management.
2. Risk to life and infrastructure due to floods and landslides			
Death and severe health effects, disruption of critical infrastructure and service systems.	More frequent and severe storms and heavy precipitation events. Changing snow conditions and thawing permafrost. Retreating glaciers, formation of glacier lakes, increased glacier lake outburst flood hazard.	More people exposed to floods and landslides due to changing hazards, land-use and increased population; occupation of more risk-prone areas such as flood plains and steep slopes.	Low income and marginal populations, low resilience of infrastructure and critical service systems. Limited government support through insurance, monitoring, early warning systems and recovery.
3. Risk of water insecurity			
Seasonal water availability change and decline due to glacier shrinkage, snow cover	Glacier shrinkage, snow cover change, more pronounced dry periods,	Increase in population dependent on contribution of glacier/snow melt,	Unequal water consumption systems, failed water management

change, more pronounced dry periods and poor or failed water management and governance.	precipitation and circulation changes.	especially during drought conditions. Increased demand from intensification of agriculture, mining, hydropower and urbanisation.	and government capacities, low water infrastructure efficiency, growing urban areas.

4. Risk of severe health effects due to increasing epidemics (in particular vector-borne diseases)

Increased rate of epidemics of vector-borne diseases (malaria, dengue, Zika, leishmaniasis) together with diarrheal diseases. Severe health effects and damage to health systems in countries with low adaptive capacity and where original endemicity is high and control status poor.	Higher temperatures increase the geographical range of vectors, leading to expansion of climate suitable areas.	Increased population density and mobility through urbanization results in high transmission rate. Increased population exposed to arboviruses due to expansion of vectors, including higher altitudes and latitudes.	Poor sanitation conditions, particularly in low-income communities and for Indigenous Peoples. Insufficient coverage of appropriate water provision and sewage systems. Low structural or economic capacity to cope; underfunding of health systems. Increase in infections can increase incidence of more severe forms of dengue.

5. Systemic risks of surpassing infrastructure and public service systems

Breakdown of public service systems, including infrastructure and health services due to cascading impacts of natural hazards and epidemics, affecting a large part of the population.	Higher frequency and magnitude of climate-related events (storms, floods, landslides) together with an increase in spatial and temporal distribution of pathogens/vectors for malaria, dengue, Zika and leishmaniasis.	More people and infrastructure exposed to climate/weather events. Increase in population exposed to arboviruses due to spatial expansion of vectors.	Increasing vulnerability of public service and infrastructure systems. Insufficient disaster management. Little improvement, maintenance and expansion of public health care systems. Low system resilience.

6. Risk of large-scale changes and biome shifts in the Amazon

Transition from tropical forest into other biomes such as seasonal forest or savannah through forest degradation and deforestation. Risk of shifting from carbon sink to source.	More frequent, stronger and persistent drought periods. Temperature increase and reduction in annual rainfall.	Reduced availability of natural sources for local people. Land use and land cover change (mining, deforestation). Loss of biodiversity and ecosystem services. Health impacts from increased forest fires particularly for Indigenous Peoples.	Strong dependence on non-climatic drivers, in particular land-use change, deforestation, forest fire practices. Low capacity to monitor and control deforestation.

7. Risk to coral reef ecosystems due to coral bleaching

Degradation and possible death of the Mesoamerican coral reef, the second largest reef in the world. Severe damage to habitat for marine species, degrading coastal protection and other ecosystem services, decreased food security from fisheries, lack of income from tourism.	Ocean sea surface temperature increase, lowered seawater pH and carbonate levels due to increased atmospheric CO_2 levels, leading to ocean acidification and coral bleaching.	Continued exposure to increased atmospheric CO_2 levels and sea surface temperatures together with destruction from coastal development, fishing practices and tourism.	Ecosystem highly sensitive to water temperature and pH fluctuations. High levels of negative human interference with reefs including runoff and pollution..

8. Risks to coastal socio-ecological systems due to sea level rise, storm surges and coastal erosion

Coastal flooding and erosion causing severe damage to coastal population and infrastructure. Loss of fisheries, reef degradation and decline in coastal protection due to increased storm surges and waves. Salt water intrusion and land subsidence.	High continuing trajectories of sea level rise. More intense and persistent coastal flooding, salt water intrusion, coastal erosion.	Coastal population growth. Increased number of people, infrastructure and services (coastal tourism) exposed; need of relocation of millions of people.	Poor planning in coastal development and infrastructure, disproportionate vulnerability and limited adaptation options for rural communities and Indigenous Peoples, increasing urbanisation in coastal cities. Large economic losses and unemployment from declining tourism.

Identification and assessment of key risks are informed by observed and projected impacts in the different sub-regions of CSA (Section 12.3). Figure 12.10 shows the summary of different levels of observed and future impacts per sub-region for different sectors, based on a detailed assessment of climate change impacts on various systems and components for the respective sector (Figure 12.9). This assessment is consistent with and complementary to the assessment in Section 12.3. A synthesis of these impacts (Figure 12.10) indicates the following: Climate change has a major impact on observed and future decline of Andean glaciers and snow (*high confidence*), and leads to degradation of permafrost and destabilization of related landscapes (*medium evidence, high agreement*). Water quality is a major concern across the region but there is *limited evidence* of impacts of climate change on water quality as well as on groundwater. Climate change has had a high impact on terrestrial and freshwater ecosystems in the NWS, SES and SWS sub-regions, and a medium impact in the other subregions but the level of confidence is varying across sub-region. Projections indicate a strong impact of climate change on these ecosystems for the future (*medium confidence: medium evidence, high agreement*). Many aspects and assets of ocean and coastal ecosystems (e.g., mangroves, coral reefs, saltmarshes) were identified to be strongly impacted by climate change, both for observed and future periods (*high confidence*) (Section 12.5.2; Figure 12.9).

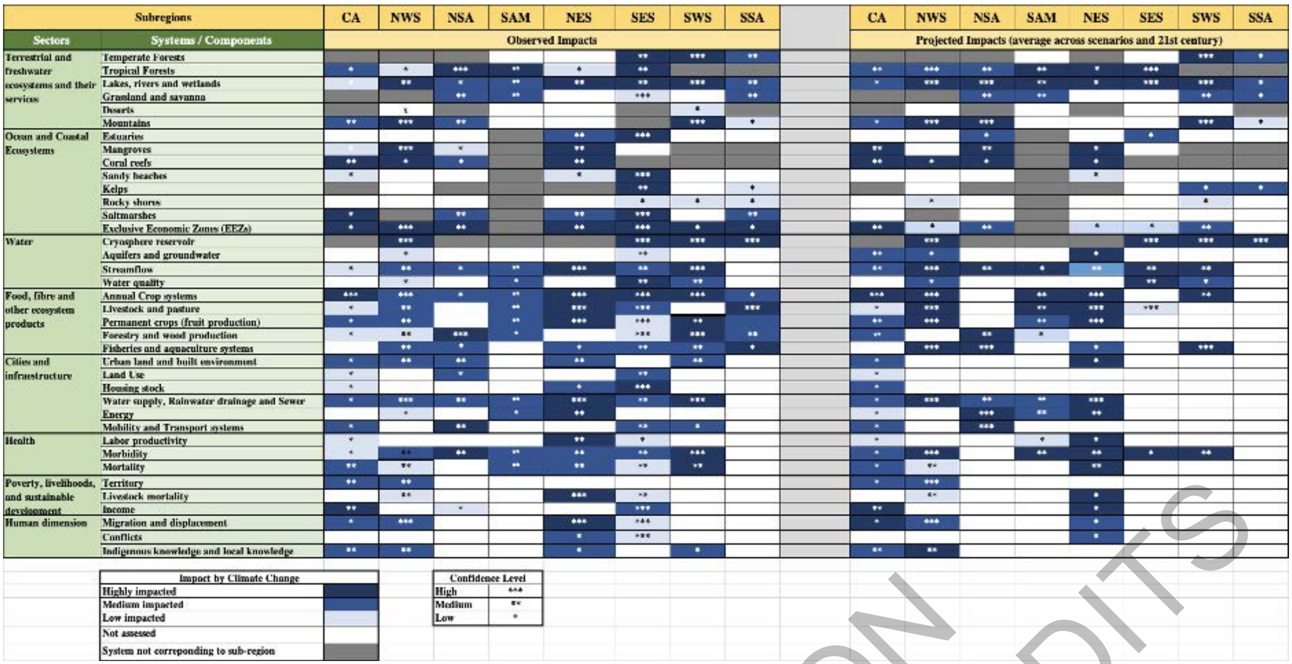

Figure 12.9: Observed and projected impacts for the subregions of Central and South America. Impacts are distinguished for main sectors and for their corresponding systems (or components). Observed impacts refer to a time-period of the last several decades. Projected impacts represent a synthesis across several emission and warming scenarios, indicative of a time-period from mid- to end of the 21st century. For each system (e.g., coral reefs) it is distinguished whether the impact of climate change is low, medium or high. The references underlying this assessment can be found in SM12.4.1.

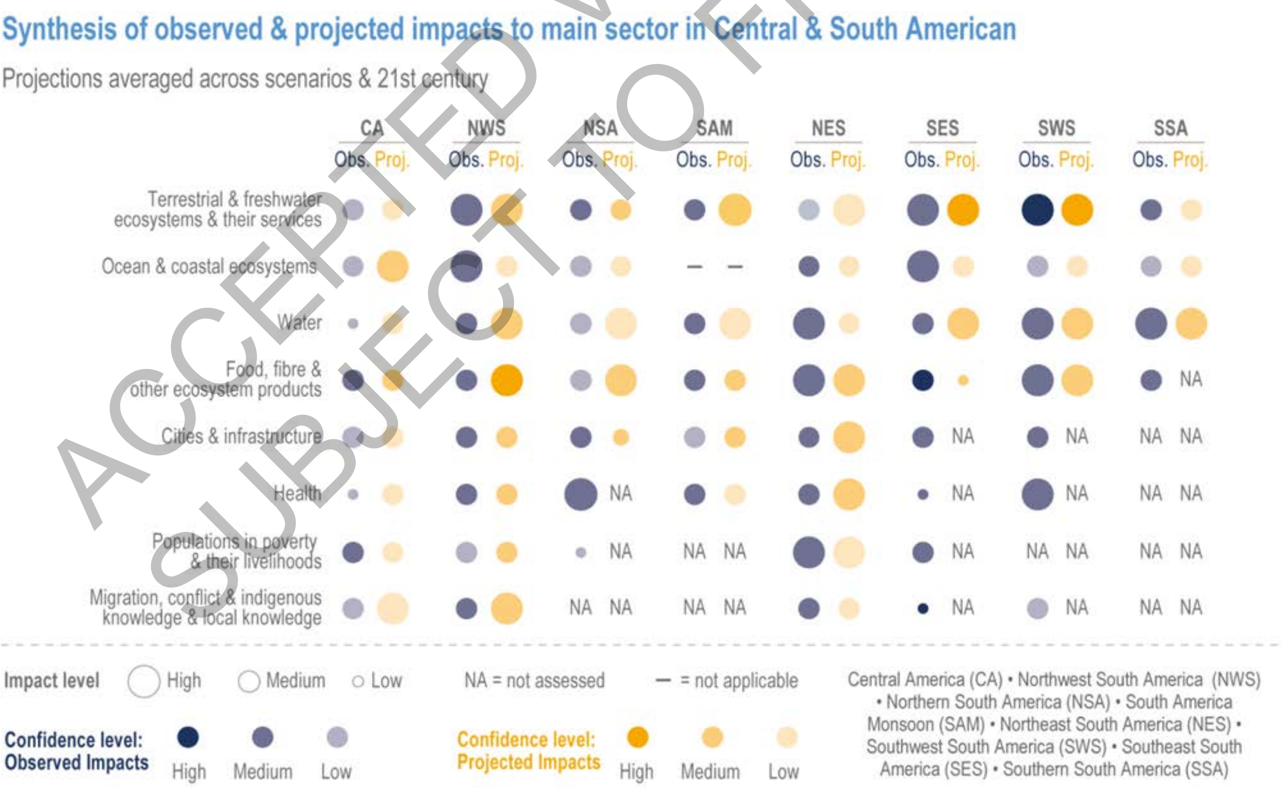

Figure 12.10: Synthesis of observed and projected impacts, distinguished for different sectors and each subregion of Central and South America. Observed impacts refer to a time-period of the last several decades. Projected impacts represent a synthesis across several emission and warming scenarios, indicative of a time-period from mid- to end of the 21st century. For each sector (e.g., health) it is distinguished whether the impact of climate change is low, medium or high. The references underlying this assessment can be found in SM12.4.1 and the methodology to complete the synthesis is found in SM12.4.2.

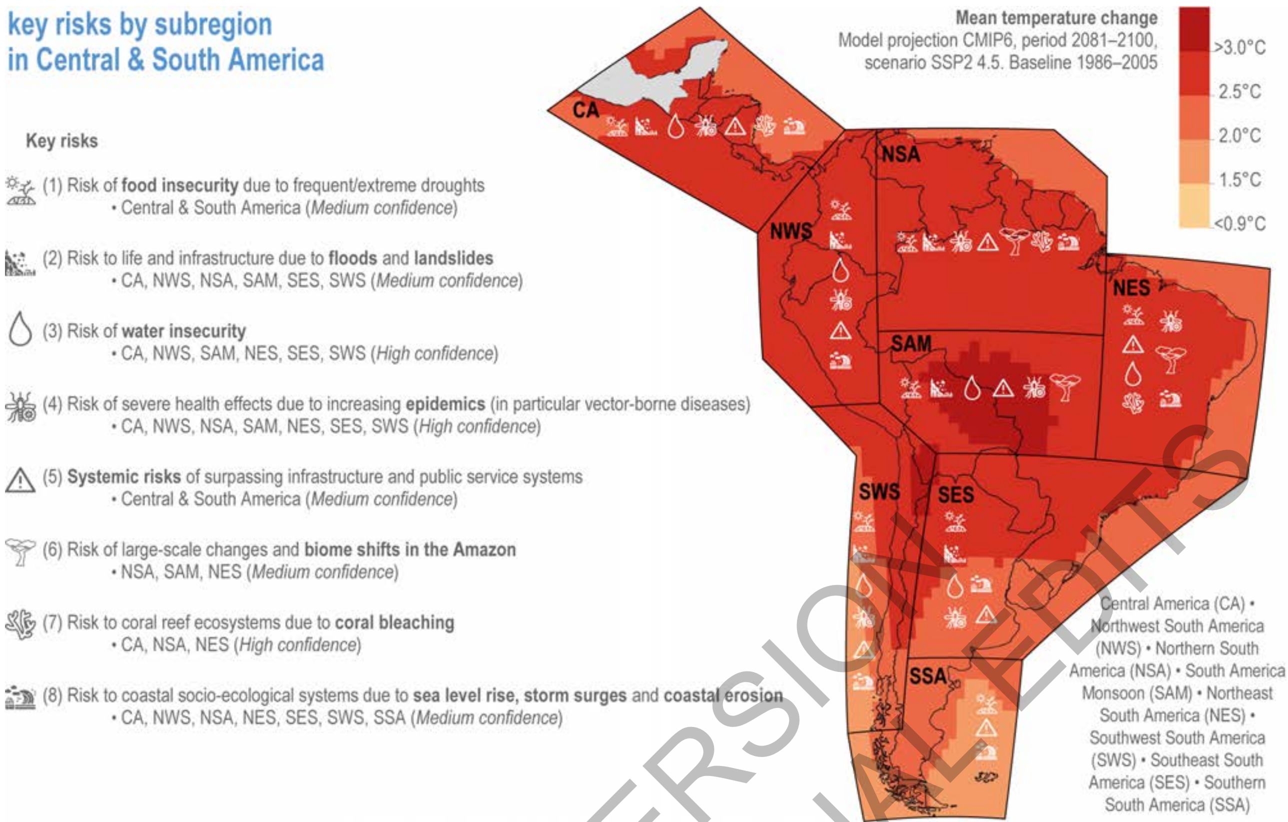

Figure 12.11: Synthesis of key risks for the Central and South America region. The base map indicates the mean temperature change between the scenario SSP2 4.5 using CMIP6 model projections for 2081-2100, and a baseline period of 1986-2005 (WGI AR6 Atlas, Gutiérrez et al., 2021).

In most sub-regions, crop, livestock, fisheries and food systems in general show medium to high impacts of climate change over the observed period and similarly for the future of the 21st century (*medium confidence: medium evidence, high agreement*). For some sub-regions, the available literature does not allow the assessment of impacts on several human systems, including cities and infrastructure, health, poverty, livelihoods, migration, conflict, Indigenous knowledge and local knowledge, especially for future time periods. This points to important knowledge gaps about climate change impacts on human systems. Indication of high impacts for several human systems and sub-regions points to the need to close these knowledge gaps.

The assessment of key observed and projected impacts and risks shows that in the CSA region several systems are already approaching critical thresholds under current warming levels, in particular glaciers in the Andes and coral reefs in Central America (*high confidence*), and further ocean and coastal ecosystems in virtually all sub-regions (*medium confidence: medium evidence, high agreement*). Some systems could cross these thresholds with different levels of reversibility depending on the degrees of future warming, namely glaciers in the Andes and coral reefs in Central America which will show partial but irreversible loss already under low levels of warming (RCP2.6) (*high confidence*). The risk of large-scale ecological changes and biome shifts of the Amazon forest, i.e., a transition from tropical forest into other biomes such as seasonal forest or savannah, is now assessed with *medium confidence*, with the extent of the changes depending on the level of future warming and non-climatic drivers (land-use change, deforestation, forest fire practices).

Systemic risks where critical infrastructure and public service system capacities are surpassed due to storms, floods and epidemics, with cascading impacts through vulnerable systems and populations and economic sectors, have the potential to affect large parts of the population and are therefore of major concern (*medium confidence: limited evidence, high agreement*). The COVID-19 crisis has exposed the existing vulnerabilities in important systems, in particular health systems and public service (Phillips et al., 2020). However, tipping points in social systems are poorly understood (Bentley et al., 2014; Milkoreit et al., 2018), and there is *limited evidence* to inform understanding about which level of compound climatic, environmental and socio-economic stressors social systems withstand in CSA.

Overall, most key risks and their severity and extent are strongly driven and determined by the system's exposure, vulnerability and adaptive capacity. In particular, the high vulnerability of large populations, infrastructure and service systems such as health, food and energy production and supply are important factors, along with high inequalities and poor governance, for creating and increasing key risks (*high confidence*). Prevailing low levels of available information and understanding exacerbate the uncertainties surrounding key risks, and hence pose limitations to adaptation. An example is Central America with high levels of vulnerability and exposure but there is *limited evidence* and understanding on impacts and risks, making this region susceptible to inappropriate adaptation to expected future climate change impacts.

12.5 Adaptation

Adaptation initiatives across the region have increased since AR5. National Communications (NC), Nationally Determined Contributions (NDC) and National Adaptation Plans (NAP) (https://unfccc.int) recently published are providing guidance for adaptation in CSA. There is also a diversity of non-governmental adaptation initiatives, both at the national and sub-national levels. In this context, this section assesses, through a sectoral approach, the main challenges, opportunities, trends and initiatives to adapt to climate change in the region.

12.5.1 Terrestrial and Freshwater Ecosystems and their Services

CSA is one of the most biodiverse regions in the World, hosting unique socio ecosystems that will be strongly impacted by climate change (*high confidence*) (Section 12.3; Cross-Chapter Paper 1; CAF, 2014; Camacho Guerreiro et al., 2016; IPBES, 2018a; Li et al., 2018; Retsa et al., 2020) . Warming has generated extreme heat events in many parts of CSA (IPCC, 2019a) that, together with droughts and floods, will seriously affect the integrity of terrestrial and freshwater ecosystems in the entire region (Section 12.3; CAF, 2014) . A reduction in net primary productivity in tropical forests and glacier retreat in the Andes, for example, are expected to cause significant negative socioecological impacts (Feldpausch et al., 2016; Lyra et al., 2017; Cuesta et al., 2019) (see Case Study, 12.7.1). Biodiversity-rich spots in the region are well assessed in the literature as compared to other regions of the World, especially for the Atlantic Forest, Mesoamerica and Cerrado (Cross-Chapter Paper 1.2.2; Manes et al., 2021) . Up to 85% of of evaluated natural systems (species, habitats and communities) in the literature for biodiversity-rich spots since AR5 were projected to be negative impacted by climate change (*high confidence*), with 26% of projections predicting species extinctions (Cross-Chapter Paper 1.2.2; Manes et al., 2021) . Indigenous knowledge and local knowledge play an important role in adaptation and are vital components of many socioecological systems, while also being threatened by climate change (*high confidence*) (Box 7.1; Valdivia et al., 2010; Tengö et al., 2014; Mistry et al., 2016; Harvey et al., 2017; Diamond and Ansharyani, 2018; Camico et al., 2021) .

12.5.1.1 Challenges and opportunities

The conversion of natural ecosystems to agriculture, pasture and other land uses in CSA has been identified as a major challenge to climate change adaptation in the region (*high confidence*) (Scarano et al., 2018; IPCC, 2019a). In the last three decades, South America has been a significant contributor of the growth of agricultural production worldwide (OECD/Food and Agriculture Organization of the United Nations, 2015), driven partly by increased international demand for commodities, especially soybeans and meat (IPCC, 2019a). Between 2001 and 2015 about 65% of all forest disturbance in the region was associated with commodity-driven deforestation (Curtis et al., 2018). High rates of native vegetation conversion in Argentina, Bolivia, Brazil, Colombia, Ecuador, Paraguay and Peru threaten important ecosystems (Amazon, Cerrado, Chacos and Llanos savannas, Atlantic rainforest, Caatinga and Yungas) (Graesser et al., 2015; FAO, 2016c). Almost 2/3 of soy consumed in EU+ comes from Brazil, Argentina and Paraguay (IDH, 2020), increasing conversion risk in the Amazon, Cerrado, and Gran Chaco. Despite growing commodities production traceability, in 2018 only 19% of the soybean meal consumed in EU+ was certified deforestation-free, and 38% compliant with the FEFAC Soy Sourcing Guidelines (IDH, 2020), which is a great challenge at the international level (Negra et al., 2014; Curtis et al., 2018; Lambin et al., 2018; IDH, 2020).

Investing in actions aimed at protection, restoration and sustainable use of biodiversity and ecosystems is a good approach for maintaining critical ecosystem services, and is part of a common strategy for adaptation, mitigation and disaster risk reduction in the region (*high confidence*) (Kabisch et al., 2016; Scarano et al., 2018). These strategies also meet the forest and water conservation international agendas, optimizing resources and solutions (Strassburg et al., 2019). Global conservation and sustainable development commitments, such as the Aichi Targets (CDB), Sustainable Development Goals (UN), the Nationally Determined Contribution (NDC) under the Paris Agreement, and the New York Declaration on Forests strongly rely on nature-based solutions (NbS) to achieve their objectives (Brancalion et al., 2019) (Figure 12.12). The COVID–19 outbreak also brought attention to the need for preserving tropical forests as a mean to prevent spill over of viruses from wildlife to humans, with concerns over that risk in the Amazon (Allen et al., 2017b; Dobson et al., 2020; IPBES, 2020; Ferreira et al., 2021). These represent an important opportunity for Ecosystem Based Adaptation (EbA) to be at the core of NbS for climate change, access finance and promote climate resilient development pathways in CSA.

The Declaration on Protected Areas and Climate Change, presented by 18 CSA countries during the UNFCCC COP21, highlights the fundamental role of protected areas in providing the “green infrastructure” needed for implementing climate change mitigation and adaptation, and safeguard the provision of essential ecosystem services and the livelihoods of Indigenous Peoples and local communities (Gross et al., 2016). Protected Areas systems in CSA are underfunded (*very high confidence*). Latin American (including Mexico) governments allocate just about 1% of national environmental budgets on protected areas (about USD 1.18 ha^{-1} on average). This figure only covers 54% of their basic needs, resulting in insufficient management. The financing gap to achieve optimal needs for protected areas in CSA is approximately USD 700 million yr^{-1} (Bovarnick et al., 2010). This seriously compromises the management and delivery capacity of protected areas for climate change adaptation, and preparedness for ongoing ecological transformation (van Kerkhoff et al., 2019). Furthermore, in order to become a relevant mechanism for resilience, protected areas need to be managed for this purpose (Mansourian et al., 2009). About 40% of protected areas in Latin America and Caribbean (including Mexico), have management effectiveness evaluations being undertaken (UNEP-WCMC and IUCN, 2020a). This is hardly representative of Aichi’s Goal 11, although far better than the 11% global average. Collaborations with the Indigenous Peoples and local communities are also an important issue to consolidate protected areas (Gross et al., 2016). In addition to protected areas as solutions for climate change adaptation and mitigation, there is also a need to protect or restore ecosystems outside the protected areas, as illustrated by the Mesoamerican Biological Corridor (Imbach et al., 2013).

Despite some local and specific assessments (e.g., Warner (2016)), there is a significant gap on identifying barriers to adaptation or maladaptation in the region (Dow et al., 2013). In their National Communications (NC), Nationally Determined Contributions (NDC) and/or National Adaptation Plans (NAP) (https://unfccc.int), most countries identified inadequate financing and access to technology as barriers for adaptation relevant to terrestrial and freshwater socio-ecosystems (*high confidence*). Insufficient institutional coordination is also frequently mentioned (Rangecroft et al., 2013; Cameron et al., 2015). These limitations could be partially addressed through multilateral cooperation, incorporation of synergies from the local to the national scales, local empowerment, and poverty alleviation (Rangecroft et al., 2013; Harvey et al., 2017; Murcia et al., 2017; Calispa, 2018; Chain-Guadarrama et al., 2018).

12.5.1.2 Governance and financing

All CSA countries have formulated policies that include measures relevant for socio-ecosystem adaptation in their NCs, NDCs and NAPs (https://unfccc.int), with an emphasis on protection and restoration of water and forests (*high confidence*). Existing proposed measures, instruments and programs, however, do not yet reflect the vision needed to integrate the ecosystem and human dimensions of vulnerability. The administration coordination and the progress in adaptive ecosystem management are incipient, due in part to the lack of stable financial resources and scientific, Indigenous knowledge and local knowledge (IK and LK) about adapting ecosystems to climate change (Bustamante et al., 2020). Brazil was an exception, showing dramatic policy-driven reduction in deforestation in the Amazon between 2004–2012, with a concomitant 70% increase in soy production, the most profitable Amazon crop (Hansen et al., 2013; Nepstad et al., 2014). Policies included territorial planning (protected areas, Indigenous territories and land tenure), satellite monitoring, market and credit restrictions on high-deforesting municipalities, plus some incentives to small farmers (Boucher et al., 2013; Hansen et al., 2013; Nepstad et al., 2014; Castelo, 2015; Cunha et al., 2016a). It is important to highlight the important role of Indigenous territories, in addition to protected areas, in forest conservation in the Amazon (*high evidence, medium agreement*) (Schwartzman et al., 2013; Barber et al., 2014; Nepstad et al., 2014; Walker et al., 2014b). These policies were partially funded by results-based compensation through the Amazon Fund. Since 2012, however, policies and institutions have weakened, and Amazon deforestation rates started to rise (Carvalho et al., 2019), sharpening in recent years (Silva Junior et al., 2021). Conservation incentives, a new complementary and allegedly cost-effective approach, is increasingly being implemented in the region (Magrin et al., 2014). They include payment for ecosystem services, REDD+, environmental certification and conservation easements, but remain controversial, and more research is needed on their effectiveness, possible negative side effects, participatory management systems and collective decision-making processes (Larson and Petkova, 2011; Locatelli et al., 2011; Pinho et al., 2014; Strassburg et al., 2014; Mistry et al., 2016; Gebara and Agrawal, 2017; Scarano et al., 2018; Ruggiero et al., 2019; To and Dressler, 2019; Vallet et al., 2019).

12.5.1.3 Adaptation options to avert and reduce key risks on terrestrial and freshwater ecosystems

Research, monitoring systems and other initiatives for knowledge management are promoted in the region on terrestrial and freshwater socio-ecosystem adaptation (*high confidence*) (NCs, NDCs and NAPs, https://unfccc.int). In Chile, for example, the Eco-social Observatory of Climate Change Effects for High Altitude Wetlands of Tarapacá has been collecting information on physical, biological and social variables since 2013 (Uribe Rivera et al., 2017). Other examples in the Andes are the GLORIA-Andes network (Cuesta et al., 2017a), the Andean Forest Network (Malizia et al., 2020) and the Initiative of Hydrological Monitoring in the Andes (IMHEA), with measures to optimize watershed management and protection, and reduce the risk of water insecurity (Correa et al., 2020).

Poverty is a driver of climate change risk, while sustainable use of ecosystems fosters adaptation (Kasecker et al., 2018) (*high confidence*). Most of 398 “Ecosystem-based Adaptation hotspots” identified in Brazil on this premise are located in some of the most vulnerable ecosystems to climate change (Kasecker et al., 2018). Although conservation and restoration is reported as effective to reduce risk (*medium confidence: medium evidence, high agreement*) (Anderson et al., 2010; Borsdorf et al., 2013; Keenan, 2015; Pires et al., 2017; Ramalho et al., 2021), their effectiveness depends on the integration of conservation actions with enhancement of local socioeconomic conditions (*medium confidence: medium evidence, high agreement*) (Scarano and Ceotto, 2015; Pires et al., 2017; Kasecker et al., 2018; de Siqueira et al., 2021; Vale et al., 2021).

Since AR5, there has been an increase in the number of adaptation measures through natural resources and ecosystem services management. The main approaches are EbA and Community-based Adaptation (CbA) (*high confidence*) (NCs, NDCs and NAPs, https://unfccc.int). IK/LK can be very detailed and usually relates to people’s priorities identified by collective decision-making (Box 7.1; (Hurlbert et al., 2019, SRCCL Section 7.6.4); SRCCL Cross-Chapter Box ILK in Chapter 13; (de Coninck et al., 2018, SR1.5 Section 4.3.5.5). In Manaus, central Amazon, fishermen perceive reductions on fish size, diversity and capture levels caused by droughts; while recognizing that floods hinders access to fishing grounds (Keenan, 2015; Camacho Guerreiro et al., 2016). In the Amazon floodplains, small-scale fisher and farmer’s communities incorporate their knowledge on natural hydrologic and ecological processes into management systems that reduce climate change risk and impacts (Oviedo et al., 2016). Smallholder grain farmers in Guatemala and Honduras implement EbA practices based on local knowledge (e.g., live fences, home gardens, shade trees in coffee plantations, dispersed trees in corn fields and other food insecurity risk reduction practices) (Harvey et al., 2017; Chain-Guadarrama et al., 2018). There is, therefore, a great potential for terrestrial and freshwater ecosystem adaptation to climate change in CSA, provided that the right incentives and sociocultural protective measures are in place (*high confidence*) (Section 12.5.10.4; Table SM12.7).

Disarticulation between policy and implementation is a common problem. Ecuadorian climate public policy points towards a CbA approach, but it is often downsized in the implementation (Calispa, 2018). Important adaptation actions have been undertaken in Argentina, Bolivia, Brazil, Chile, Colombia, Ecuador, El Salvador, Paraguay, Peru and Uruguay; both in policymaking and institutional arrangements, but they tend to be poorly coordinated with policies on development, land planning and other sectoral policies (Ryan, 2012). Some type of community participation mechanisms is present in most country strategies, but their levels of implementation vary considerably (*medium confidence: medium evidence, high agreement*) (Ryan, 2012; Pires et al., 2017; Calispa, 2018).

There is an ecosystem bias in adaptation priorities for research and implementation, hindering the development of comprehensive adaptation programs. Most scientific research on adaptation in Peru focuses on the highlands and coastal regions while mitigation research focuses on forests (Chazarin et al., 2014). Combined adaptation and mitigation strategies can produce positive results, but they are often disconnected (Locatelli et al., 2015). Most reviewed cases in agriculture and forestry in Latin America (84% of 274 cases) reported positive synergies between adaptation and mitigation. Nevertheless, research on Latin American forests tend to focus on mitigation, while studies on agriculture are usually oriented towards adaptation (*high confidence*) (Locatelli et al., 2015; Locatelli et al., 2017).

Rural communities in the Cusco Region, Peru, ground their ability to adapt to climate change on four cultural values, known in Quechua as ayni (reciprocity), ayllu (collectiveness), yanantin (equilibrium) and chanincha (solidarity), but policies oriented towards “modernization” undermine these traditional mechanisms. Adaptation strategies could benefit from integrating these and other insights from traditional cultures, fostering risk reduction and transformational adaptation towards intrinsically sustainable systems (*medium confidence: medium evidence, high agreement*) (Walshe and Argumedo, 2016).

Protected areas have become an important component as enablers of national climate change adaptation strategies. They increase ecosystem’s adaptive potential, reducing climate risk and delivering numerous ecosystem services, sustainable development benefits while playing an important role in climate change mitigation (*high confidence*) (Mackey et al., 2008; Dudley et al., 2010; Gross et al., 2016; Bebber and Butt, 2017; Dinerstein et al., 2019; IPCC, 2019a). CSA already has a greater percentage of land (24.1%) under protected status than the world average (14.7%) (UNEP-WCMC and IUCN, 2020b). Some countries, including Belize, Bolivia, Brazil, Guatemala, Nicaragua and Venezuela already met or surpassed the 30% CDB and IUCN goal (Dinerstein et al., 2019), and others like Costa Rica and Honduras are very close to doing so. In some cases, the establishment of protected areas not accompanied by collective decision-making processes has displaced local people or denied them access to natural resources, increasing their vulnerability to climate change (Brockington and Wilkie, 2015).

In addition to better managing and expanding protected areas networks, Other Effective Area-based Conservation Measures (OECMs), recently defined by the Parties to the Convention on Biological Diversity (Dudley et al., 2018), could also enhance ecosystem resilience (*low confidence*). Private Protected Areas in the mountain regions of the Americas (e.g., Andes), play an important role in closing the gaps in fragmented biomes and expanding protection in underrepresented areas (Hora et al., 2018). In Brazil, there is also a huge potential for conservation and sustainable management in private areas, as roughly 53% of the country’s native vegetation is within private land (Lapola et al., 2014; Soares-Filho et al., 2014).

Large-scale restoration is also seen as pivotal to limiting both climate change (IPCC, 2019a) and species extinction (IPBES, 2018a) (*very high confidence*). A new multi-criteria approach for optimizing multiple restoration outcomes (for biodiversity, climate change mitigation, and cost), for example, indicate that South America has the greatest extension of converted lands, evenly distributed in the top 50% of global priorities (Strassburg et al., 2020).

12.5.2 Ocean and Coastal Ecosystems and their Services

Ocean and coastal ecosystems provide suitable habitats to a high number of species that support important local fisheries, the tourism sector and the economy of the region (*high confidence*) (Section 3.5; Table 3.9; González and Holtmann-Ahumada, 2017; Venerus and Cedrola, 2017; CEPAL, 2018; Carvache-Franco et al., 2019; SROCC Section 5.4 Bindoff et al., 2019). There is *high confidence* that CSA ocean and coastal ecosystems are already impacted by climate change (Figure 12.9, 12.10; Table SM12.3; Section 3.4; , Section 5.4 in SROCC, Bindoff et al., 2019), and highly sensitive to non-climate stressors (Figure 12.8; Table SM12.3; Section 3.4). Projections for CSA ocean and coastal ecosystems alert about significant and negative impacts (*high confidence*) which include major loss of ecosystem structure and functionality, changes in the distributional range of several species and ecosystems, major mortality rates, and increasing number of coral bleaching events (Figure 12.9; Figure 12.10; Table SM12.3; Section 3.4; SROCC Sections 5.3, 5.4, Bindoff et al., 2019).

CSA subregions are highly dependent on ocean and coastal ecosystems, and thus vulnerable to climate change (FAO, 2018). Fisheries and aquaculture contribute significantly to food security and livelihoods by creating employment (more than two million people), income and economic growth for the region (Section 3.5; FAO, 2018) (). More than 45% of the total fisheries in CSA are based on marine products (CEPALSTAT, 2019). Peru, Chile, Argentina and Ecuador are among the 15 countries with the largest marine capture production worldwide (Gutiérrez et al., 2016a; FAO, 2018; Vannuccini et al., 2018), while more than 90% of the hydrological resources produced by aquaculture in CSA have a marine origin (CEPALSTAT, 2019). There is *high confidence* about important current and future impacts of climate change hazards in marine resources subjected to fisheries, however there is *low evidence* about the impacts on regional economies (Figure 12.9, 12.10; Table SM12.3).

12.5.2.1 Adaptation measures and strategies applied on oceans and coasts of CSA

Similar to those pointed by WGII AR5 Chapter 27 (Magrin et al., 2014) and Chapter 3 (Section 3.5; Section 3.6.2; Box SLR in Chapter 3), adaptation strategies in ocean and coastal ecosystems in CSA are still focused on the ecosystem protection and restoration, and the sustainable use of marine resources (*high confidence*). There is *low evidence* about how coastal urban areas and touristic settlements of CSA countries are adapting to SLR and extreme events (Calil et al., 2017; Villamizar et al., 2017). Some of this strategies include planned relocation (Dannenberg et al., 2019) and the use of grey infrastructures as seawalls and bulkheads (Silva et al., 2014; Isla et al., 2018) .

There is *medium confidence* that Ecosystem-based Adaptation (EbA) is the main strategy used in CSA coral reefs ecosystems. The set of strategies applied include the protection, restoration (e.g., coral gardening, larval propagation), and conservation of coral reefs areas through the application of the spatial ocean zoning schemes such as Marine Protected Areas (MPAs), marine managed areas (MMAs), National Parks, Wildlife Refuges, Special Zones of Marine Protection, Special Management Zones, Responsible Fishing Areas, and the establishment of management plans with some level of participatory processes. These strategies are complemented with actions that promote the development of research and education programs, recreational and cultural activities, the use of community-based approaches, and the creation of national specific laws (Graham, 2017) and the adhesion of international treaties (e.g., Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITIES), AGENDA 21, United Nations Convention on the Law of the Sea (UNCLOS), Ramsar Convention on Wetlands of International Importance Especially as Waterfowl Habitat) (Cruz-Garcia and Peters, 2015; Gopal et al., 2015; Graham, 2017; Bayraktarov et al., 2020).

Adaptation measures in mangroves ecosystems are mainly focused on the application of EbA strategies (*high confidence*). This measures include the application of restoration programs, the creation of management plans (which also have significant co-benefits with mitigation (Section 3.6.2.1), and the establishment of coastal protected areas, followed by the development of research activities, the creation of specific mangrove policies through new laws and resolutions (e.g., Colombia) (Cvitanovic et al., 2014; Krause, 2014; Blanco-Libreros and Estrada-Urrea, 2015; Carter et al., 2015; Estrada et al., 2015; Ferreira and Lacerda, 2016; Oliveira-Filho et al., 2016; Rodríguez-Rodríguez et al., 2016; Alvarado et al., 2017; Álvarez-León and Álvarez Puerto, 2017; Baptiste et al., 2017; Borges et al., 2017; Jaramillo et al., 2018; Salazar et al., 2018; Armenteras et al., 2019; Blanco-Libreros and Álvarez-León, 2019; Maretti et al., 2019; Ellison et al., 2020)

The use of territorial planning tools, the promotion of sustainable resource exploitation, the adherence to certification schemes, and the implementation of management instruments such as Ecosystem-based Management (EbM) followed by the use of an integrated coastal zone management, coastal marine spatial planning, capacity building, ecological risk assessments have been the mains strategies used to ensure the sustainability of marine resources subjected to fisheries across EEZs of CSA (*high confidence*) (Hellebrandt et al., 2014; Gelcich et al., 2015; Singh-Renton and McIvor, 2015; Gutiérrez et al., 2016a; Karlsson and Bryceson, 2016; Oyanedel et al., 2016; Debels et al., 2017; Isaac and Ferrari, 2017; Mariano Gutiérrez et al., 2017; Barragán and Lazo, 2018; Bertrand et al., 2018; Lluch-Cota et al., 2018; Guerrero-Gatica et al., 2020).

Other strategies include the application of local regulations (e.g., closed seasons) (Fontoura et al., 2016), and the use of participative instances (Hellebrandt et al., 2014; Arroyo Mina et al., 2016; Matera, 2016).

12.5.2.2 Adaptation success in ocean and coastal ecosystems of CSA

There is *low evidence* about how the strategies and actions taken and implemented in ocean and coastal systems of CSA have contributed to advance in the protection and conservation of ocean and coastal ecosystems. However, some important advances are visible in Colombian Pacific areas with coral reefs (new conservation plans, research monitoring and conservation practices) (*low confidence*) (Cruz-Garcia and Peters, 2015; Alvarado et al., 2017; Bayraktarov et al., 2020). In Panama, actions taken have allowed the protection of a high number of marine areas with coral reefs, as well as the incorporation of management approaches that include several sectors such as fisheries, tourism, coral protection and coral conservation (*low confidence*) (Alvarado et al., 2017). In the case of Costa Rica, 80% of coral habitats are located inside of MPAs, multiple research coral-related activities have been performed, and several training activities have favoured the engagement of the local community in their protection against climate and non-climate hazards (*low confidence*) (Alvarado et al., 2017).

There is *low evidence* of how the incorporation of mangroves as Ramsar sites, the reforms of legislations (e.g., fines and stronger regulations), and the creation of reserves and private protection initiatives (e.g., Belize Association of Private Protected Areas BAPPA), and capacity-building projects or new educational programs have promoted the protection of mangroves in CSA countries such as Honduras, Guatemala and Belize (Cvitanovic et al., 2014; Carter et al., 2015; Ellison et al., 2020). In Brazil, between 75–84% of mangroves are under some level of protection which has improved the forest structures, and multiple research programs (e.g., Mangrove Dynamics and Management, MADAM, and 'GEF-Mangle') have been developed (*medium confidence*) (Krause, 2014; Medeiros et al., 2014; Estrada et al., 2015; Ferreira and Lacerda, 2016; Oliveira-Filho et al., 2016; Borges et al., 2017; Maretti et al., 2019; Strassburg et al., 2019). In Colombia, research projects (e.g., Mangroves of Colombia Projects, MCP), the installation of a geographic information system for mangroves (e.g., SIGMA Sistema de Información para la Gestión de los Manglares en Colombia), surveillance monitoring plans (e.g., EGRETTA Herramientas para el Control y Vigilancia de los Manglares), and the establishment of protected areas have contributed to decrease loss of the mangrove forest (*high confidence*) (Blanco-Libreros and Estrada-Urrea, 2015; Rodríguez-Rodríguez et al., 2016; Álvarez-León and Álvarez Puerto, 2017; Baptiste et al., 2017; Jaramillo et al., 2018; Salazar et al., 2018; Armenteras et al., 2019; Blanco-Libreros and Álvarez-León, 2019).

There is *low evidence* whether the establishment of MPAs and the creation of legal instruments have allowed the development of new research activities have increased the environmental awareness, decreased the illegal extraction, and improved the local coordination which have promoted the sustainable use of marine resources, and improved the community-government cooperation in marine ecosystems (Alvarado et al., 2017). The experience in countries like Chile demonstrates the importance of implementing robust management plans that guarantee the protection objectives and the sustainability through the implementation of EbA measures such as MPAs (Petit et al., 2018).

There is *low confidence* about how measures adopted are ensuring the sustainability of marine resources subjected to fisheries. In Peru, the industrial fishery follows an adaptive management approach (i.e., stock assessments, catch limits), while in Chile, the small-scale fishery of benthic-demersal resources is managed through the granting of exclusive territorial use rights (called TURFS) with established quotas defined by the central authority (Bertrand et al., 2018). In addition, MPAs in Chile are playing a key role in climate change adaptation for fisheries (*medium confidence*) (Gelcich et al., 2015; Petit et al., 2018), and an increasing amount of funds have been invested in initiatives to reduce the vulnerability of fishery and aquaculture sectors to climate change (OECD, 2017). Since 2016, Argentina has been developing a strategy to implement EbM on fisheries with support from the Global Environment Facility program (GEF). Also, Argentina and Chile, are promoting the local consumption of seafood and the certification of its fishery products (OECD, 2017), while Brazil and Chile have advanced in their actions to climate change through the development of new research studies and methodologies incorporating research institutions (Nagy et al., 2015). Uruguay is incorporating stakeholders in their climate change adaptation strategies (*low confidence*) (Nagy et al., 2015), while Colombia is supporting the capacity building of fishers promoting livelihood diversification to increase the resilience of the sector (*medium confidence: medium evidence, high agreement*) (Hellebrandt et al., 2014; Arroyo Mina et al., 2016; Matera, 2016). Chile and Peru have showed certain advances in the development of guidelines for the management of the coast line and the implementation of the EbM which has favoured the collaboration of diverse and multiple stakeholders (fishers, academics, municipal institutions), the development of outreach and educational activities, and the creation of networks, and the interest of other fishery communities to implement EbM (*medium confidence: medium evidence, high agreement*) (Hellebrandt et al., 2014; Gelcich et al., 2015; Gutiérrez et al., 2016a; Oyanedel et al., 2016; Guerrero-Gatica et al., 2020). In countries like Peru and Chile, there is an increasing presence of intergovernmental and international cooperation agencies, and new funding (e.g., GEF), and projects (Inter-American Development, SPINCAM) related to change adaptation for the fishery sector (*medium confidence: medium evidence, high agreement*) (Galarza and Kámiche, 2015; Barragán and Lazo, 2018).

12.5.2.3 National climate change commitments for ocean and coasts

Beyond the protection, conservation and climate change adaptation strategies implemented on CSA ocean and coastal areas and their ecosystems, a high number of adaptation goals to face climate change impacts on ocean and coastal ecosystems and their services are incorporated in most of the national climate change adaptation commitments of CSA countries (Table 12.7).

Table 12.7: National plans with adaptation goals for ocean and coasts in CSA.

CSA country	Adaptation Initiatives	Year
Argentina	Plan Nacional de Adaptación y Mitigación al Cambio Climático[1]	2019
Brazil	National Adaptation Plan to Climate Change (Volume 1); General Strategies[2]	2016
	National Adaptation Plan to Climate Change (Volume 2); Sectoral and thematic strategies[3]	2016
Chile	Plan Nacional de Adaptación al Cambio Climático[4]	2014
	Plan Sectorial de Adaptación al Cambio Climático en Biodiversidad[5]	2014
	Plan Sectorial de Adaptación al Cambio Climático en Pesca y Acuicultura[6]	2015
	Plan de Adaptación y Mitigación de los Servicios de Infraestructura al Cambio Climático[7]	2017
	Plan de Adaptación al Cambio Climático Sector Salud[8]	2017
Colombia	Plan Nacional de Adaptación al Cambio Climático[9]	2016
Costa Rica	Política Nacional de Adaptación al Cambio Climático[10]	2018
Ecuador	Plan Nacional de Cambio Climático[11]	2015
El Salvador	Plan Nacional de Cambio Climático[12]	2015
Guatemala	Plan de Acción Nacional de Cambio Climático[13]	2018

Current goals in national and sectoral adaptation plans attempt to promote research and monitoring (e.g., new research actions, modelling, knowledge management), the development of new legislation tools and policies (e.g., inter-institutional and territorial coordination, improvement of public policies), the conservation of ocean and coastal ecosystems and their biodiversity (e.g., new MPAs establishment, protection tools), the management of climate risks (e.g., alert systems), the management of productive activities (e.g., diversification of resources), the promotion of the construction of new infrastructure and technology (e.g., grey-green infrastructure - GGI), the creation of new financial tools (e.g., insurances), the improvement of the capacity building (e.g., education, awareness), the management of water and residues (e.g., sewages and freshwater availability), the social inclusion (e.g., strategies to support vulnerable sectors, gender inclusion), and the incorporation of traditional practices (e.g., restoring traditional practices including Indigenous knowledge). However, the amount and the type of adaptation goals per country differ enormously among countries (Figure 12.12).

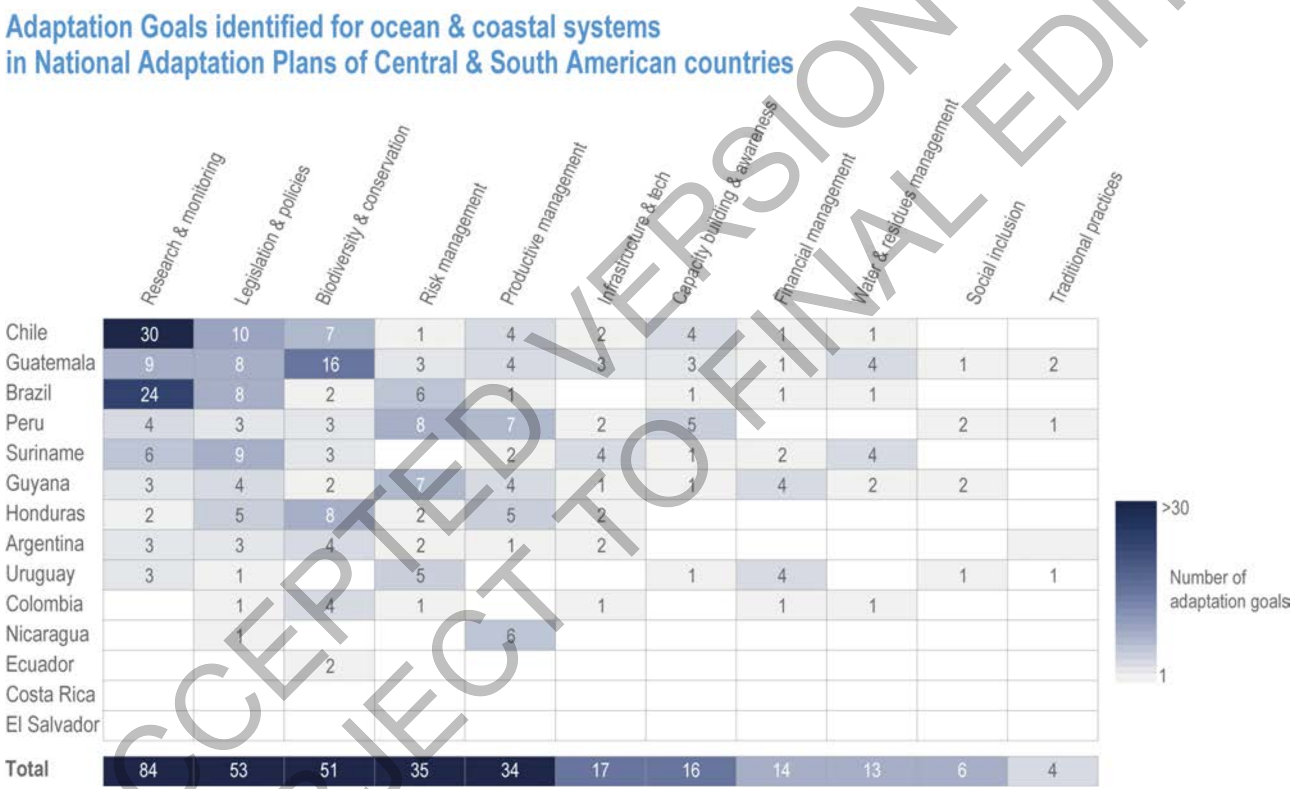

Figure 12.12: Type and amount of adaptation goals identified in National Adaptation Plans for ocean and coastal systems of CSA countries.

12.5.2.4 Limits and barriers for adaptation in ocean and coastal ecosystems

Although current national adaptation plans and many other actions and strategies are focused on improving the conservation and restoration of ocean and coastal ecosystems, as well as, the suitability of marine resources along CSA, these measures are still not able to reduce the vulnerability and sensitivity of these ecosystems to climate change hazards (*high confidence*) (Figure 12.6; Table SM12.3; Leal Filho, 2018; Nagy et al., 2019) . There is *high confidence* that sandy beaches ecosystems of CSA countries show an important loss of dunes as a consequence of the construction of infrastructures which have generate an interruption of the natural dynamic of beaches decreasing the protection to tides, waves, extreme events or tsunamis (*high confidence*) (Amaral et al., 2016; Bernardino et al., 2016; González and Holtmann-Ahumada, 2017; Obraczka et al., 2017). Also, adaptation measures to cope with SLR and coastal extreme events sometimes fail as they exacerbate coastal erosion and damage (*medium confidence: medium evidence, high agreement*) (Spalding et al., 2014; Lins-de-Barros and Parente-Ribeiro, 2018). There is *medium evidence* but *high agreement* that the most barriers limiting the success of adaptation strategies in ocean and coastal systems in CSA are due to the lack of coordination (e.g., absence of participatory processes, overlapping among fishing and protection activities), the lack of knowledge (e.g., poor monitoring, poor control and surveillance, no long-term studies), lack of adequate metrics for evaluating adaptation actions informing decision-makers hinder the continuity and adjustment of measures, weak governance (e.g., perverse incentives, resource overexploitation, conflicts), lack of financial resources and long-term commitments (e.g., crisis, lack of budgets, market fluctuations), weak policies, cultural constraints, poverty, low flexibility, lack of awareness of climate risks, and lack of engagement by stakeholders (Leal Filho, 2018; Nagy et al., 2019; Moreno et al., 2020b; Aburto et al., 2021).

Some important limits and barriers have been detected for productive systems such as fisheries and tourism in CSA (*medium confidence: medium evidence, high agreement*). Brazilian major fisheries management do not follow an ecosystem approach, although some small-scale fisheries apply a precautionary approach (Singh-Renton and McIvor, 2015). The management of Peruvian artisanal (medium and small-scale fisheries) are minimal with an important lack of regulations, control, and management actions (Bertrand et al., 2018). In Argentina, marine recreational fisheries have been largely unregulated with a lack of monitoring programs which have contributed to the overexploitation of some key coastal stocks (Venerus and Cedrola, 2017). Moreover, the participation of women fishers in CSA is not equally considered being excluded from the decision-making processes (FAO, 2016b; Bruguere and Williams, 2017). Due to the lack of monitoring programs, it is unknown how this tourism industry will respond to long-term changes driven by climate change (Weatherdon et al., 2016).

12.5.2.5 Challenge and Opportunities

There is *low evidence and high agreement* that empower the local stakeholders (e.g., multilateral fisheries agreements) improve the public awareness and simplify regulations and increase the flexibility and sustainability of marine resources subjected to fisheries under future scenarios (Weatherdon et al., 2016; Kalikoski et al., 2019). Ecosystem-Based Fishery Management (EBFM) arises as a suitable tool to minimize the risk to climate change, avoid the degradation of the ecosystems and its services (Gullestad et al., 2017) and maintain the long-term socioeconomic benefits when include climate complexity and the relationships among species within the ecological systems (Long et al., 2015). There is *high confidence* that EbA is more successful and feasible than hard coastal defences for the protection, management and restoration of ocean and coastal ecosystems and their resources (Spalding et al., 2014; González and Holtmann-Ahumada, 2017; Scarano, 2017).

There is *high confidence* that ecological and social resilience is improved by the presence of adequate metrics evaluating adaptation measures that allow dynamic changes, increasing basic research and climate data (Moreno et al., 2020b), the existence of early warning systems, improved local institutions, the construction of adequate infrastructure, major funding for capacity building, and the enhanced engagement and empowerment of women (FAO, 2016b; Harper et al., 2017; Frangoudes and Gerrard, 2018; Gallardo-Fernández and Saunders, 2018; Leal Filho, 2018).

12.5.3 Water

CSA is one of the regions most affected by current and future hydrological risks to water security with an increasing number of vulnerable people depending on water from mountain (*high confidence*) (Sections 4.3, 4.4, 4.5; Immerzeel et al., 2020; Viviroli et al., 2020; WWAP, 2020). Adaptation to changing water availability is therefore a priority, but most efforts are documented only in the grey literature (e.g., governmental documents, project reports) with highly variable standards of quality and evidence. Most of the documented adaptation initiatives are in an early planning or implementation stage and evidence on successful outcomes is quite limited (Berrang-Ford et al., 2021). However, the growing number of adaptation initiatives across the CSA region has contributed to improved understanding of complex interlinkages of climate change, human vulnerabilities, local policies, and feasible adaptation approaches (McDowell et al., 2019).

12.5.3.1 Challenges and opportunities

In several regions of CSA, water scarcity is a serious challenge to local livelihoods and economic activities. Particularly (seasonally) dry regions, partly with large populations and increasing water demand, exhibit major water stress. These include the dry corridor in CA, coastal areas of Peru (SWS) and Northern Chile (SWS), the Bolivian-Peruvian Altiplano (NWS, SAM), the Dry Andes of Central Chile (SWS),Western Argentina and Chaco in Northwest Paraguay (SES), and Sertão in Northeast Brazil (NES) (*high confidence*) (Kummu et al., 2016; Mekonnen and Hoekstra, 2016; Schoolmeester et al., 2018). In NWS and SWS, downstream areas are increasingly affected by decreasing and unreliable river runoff due to rapid glacier shrinkage (*high confidence*) (Table SM12.6; Carey et al., 2014; Drenkhan et al., 2015; Buytaert et al., 2017). Many regions in CSA rely heavily on hydroelectric energy, and as a result of rising energy demand, hydropower capacity is constantly extended (Schoolmeester et al., 2018). Worldwide, SA features the second-fastest growth with about 5.2 GW additional annual capacity installed in 2019 (IHA, 2020). This development requires additional water storage options, which entail the construction of large dams and reservoirs with important social-ecological implications. River fragmentation and corresponding loss of habitat connectivity due to dam constructions have been described for e.g., the NSA, SAM, NES and SES (*high confidence*) (Grill et al., 2015; Anderson et al., 2018a) with important implications for freshwater biota, such as fish migration (*medium confidence*) (Pelicice et al., 2015; Herrera-R et al., 2020). Furthermore, examples in e.g., the NWS (Carey et al., 2012; Duarte-Abadía et al., 2015; Hommes and Boelens, 2018) and SWS (Muñoz et al., 2019b) showcase unresolved water-related conflicts between local villagers, peasant communities, hydropower operators and governmental institutions in a context of distrust and lack of water governance (*high confidence*).

Increasing water scarcity is also shaped by poor water quality, which has barely been assessed in CSA. Declining water quality can be observed e.g., due to intense agricultural and industrial activities in SWS, SES and SSA (*medium confidence*) (Mekonnen et al., 2015; Gomez et al., 2021), mining in Andean headwaters (NWS, SWS and Western SAM) and tropical lowlands (Eastern SAM and NSA) (*medium confidence*) (Bebbington et al., 2015 risk and climate resilience; Vuille et al., 2018), urban domestic use (Desbureaux and Rodella, 2019), decreasing meltwater contribution (Milner et al., 2017) and acid rock drainages from recently exposed glacial sediments (Santofimia et al., 2017; Vuille et al., 2018). The level of water pollution is often exacerbated by missing water treatment infrastructure and low governance levels (*medium confidence*) (Mekonnen et al., 2015) with considerable negative implications for human health (Lizarralde Oliver and Ribeiro, 2016).

Water scarcity risks are projected to affect a growing number of people in the near and mid-term future in view of growing water demand in most regions (*medium confidence: medium evidence, high agreement*) (Veldkamp et al., 2017; Schoolmeester et al., 2018; Viviroli et al., 2020), expected precipitation reductions in Western and Northern SAM and SWS (*medium confidence: medium evidence, medium agreement*) (Neukom et al., 2015; Schoolmeester et al., 2018), substantial vanishing of glacier extent in NWS, SAM and SWS (Table SM12.6; Rabatel et al., 2018; Vuille et al., 2018; Cuesta et al., 2019; Drenkhan et al., 2019), and increasing evaporation rates in CA (*medium confidence*) (CEPAL, 2017). Furthermore, flood risk is a serious concern (Arnell et al., 2016) and expected to increase especially in NWS, SAM, SES and SWS in the mid and long-term future (*high confidence*) (Arnell and Gosling, 2016; Alfieri et al., 2017).
Risks of water scarcity and flood are threatening people unevenly across the region. In CSA, about 26% (130 million people) of the population have no access to safe drinking water and strong disparities prevail regarding its spatial distribution, e.g., in Chile 99% of the population have access, compared to 50% in Peru, 73% in Colombia, 52% in Nicaragua or 56% in Guatemala (*high confidence*) (UNICEF and WHO, 2019). Inequalities can be further exacerbated by unregulated or privately owned water rights and allocation systems (e.g., in Chile) (Muñoz et al., 2020a). The most vulnerable people belong to low-income groups in rural areas and informal settlements of large urban areas (*high confidence*) (WWAP, 2020).

Considerable uncertainties remain concerning future hydrological risks that strongly depend on the respective pathways of human intervention, management, adaptation and socioeconomic development. The combination of (seasonally) reduced water supply, growing water demand, declining water quality, ecosystem deterioration and habitat loss, and low water governance could lead to increasing competition and conflict associated with high economic losses (*high confidence*) (Vergara et al., 2007; Vuille et al., 2018; Desbureaux and Rodella, 2019). This situation threatens human water security on the long term and poses an increasing risk to adaptation success in CSA (*high confidence*) (Drenkhan et al., 2015; Huggel et al., 2015b; Urquiza and Billi, 2020a).

Important progress has been made on climate change and water management policies in combination with more inclusive stakeholder processes. For instance, the implementation of NDCs in most countries of the region provides an important baseline for improving water efficiency, quality and governance at multi-sectoral level, and thus long-term adaptation planning (UNEP, 2015).

12.5.3.2 Main concepts and approaches

Adaptation in the water sector includes a broad set of responses to improve and transform, among others, water infrastructure, ecosystem functions, institutions, capacity building and knowledge production, habits and culture, and local-national policies (Section 4.6).

Most adaptive water management approaches in CSA centre around extending the water supply side including large infrastructure projects. However, 'hard path' interventions are now strongly contested due to negative effects exacerbating local water conflicts (Carey et al., 2012; Boelens et al., 2019; Drenkhan et al., 2019), potentially leading to increasing water demand, vulnerabilities and water shortage risks (Di Baldassarre et al., 2018), and, hence, limiting adaptive capacity (*high confidence*) (Ochoa-Tocachi et al., 2019). More integrated approaches focus on multi-use of water storage with shared stakeholder vision, responsibilities, rights and costs, as well as risks and benefits, and often integrating water and risk management (Branche, 2017; Haeberli et al., 2017; Drenkhan et al., 2019). In this chapter, a feasibility assessment was carried out for six major dimensions of multi-use water storage for the entire CSA (see Table 12.11). While geophysical and economic aspects allow for the implementation of water storage projects with multi-use approach, the institutional, social and environmental dimensions pose a major barrier (see Section 12.5.3). Further demand-oriented approaches focus on incentives for the reduction of water use through changes in people's habits, efficiency increase and smart water management (Gleick, 2002). These are promoted in some regions, such as in CA and NWS (e.g., Colombia, Ecuador and Peru), to foster a sustainable water culture (Bremer et al., 2016; Paerregaard et al., 2016).

Major attention has been put on nature-based solutions (NbS), i.e., catchment interventions that are inspired and supported by nature and leverage natural processes and ecosystem services to contribute to the improved management of water. NbS potentially enhances water infiltration, groundwater recharge and surface storage, contributes to disaster risk reduction and can replace or complement grey (i.e., conventionally built) infrastructure that is often socio-environmentally contested (WWAP, 2018). Some examples include the reactivation of ancestral infiltration enhancement systems in the Peruvian Andes (NWS) (Ochoa-Tocachi et al., 2019), the use of erosion control structures in the Bolivian Altiplano (SAM) (Hartman et al., 2016), and the potential improvement of drinking water quality and flood risk reduction in urban areas of CSA (Tellman et al., 2018, Section 12.5.5.3.2). Additionally, NbS in combination with ecosystem and community-based adaptation potentially generate important co-benefits including increasing water security and the attenuation of social conflicts in Chile (SWS) (Reid et al., 2018), water conservation in coastal Peru (NWS), and flood protection in Guyana (NSA) (*medium confidence: medium evidence, medium agreement*) (Spencer et al., 2017). However, evaluation of implementation success of NbS is often hampered by limited evidence on actual benefits (WWAP, 2018).

In recent years, the inclusion of Indigenous knowledge (IK) and local knowledge (LK) into current adaptation baselines has gained increasing attention, particularly in regions with a high share of Indigenous Peoples (NWS, SAN, SWS, NSA) (*high confidence*) (Reyes-García et al., 2016; Schoolmeester et al., 2018; McDowell et al., 2019). One example is the adapted use of agrobiodiversity when dealing with more frequent and intense tidal floods in the Amazon delta (NSA) (Vogt et al., 2016). In another context, IK and LK have been considered for the evaluation of water scarcity and glacier lake outburst flood risks in Peru (NWS) (Motschmann et al., 2020b). Additionally, local citizen science based initiatives (Buytaert et al., 2014; Tellman et al., 2016; Njue et al., 2019) can support the production of multiple knowledge with flexible and extensive data collection. Important questions centre around how to integrate IK, LK and other types of knowledge from the early planning stages on, to achieve enhanced or transformational adaptation building on co-produced knowledge (Kates et al., 2012; Klenk et al., 2017). NbS combined with community engagement and integration of diverse knowledge can foster transformational adaptation of social-ecological systems (Palomo et al., 2021).

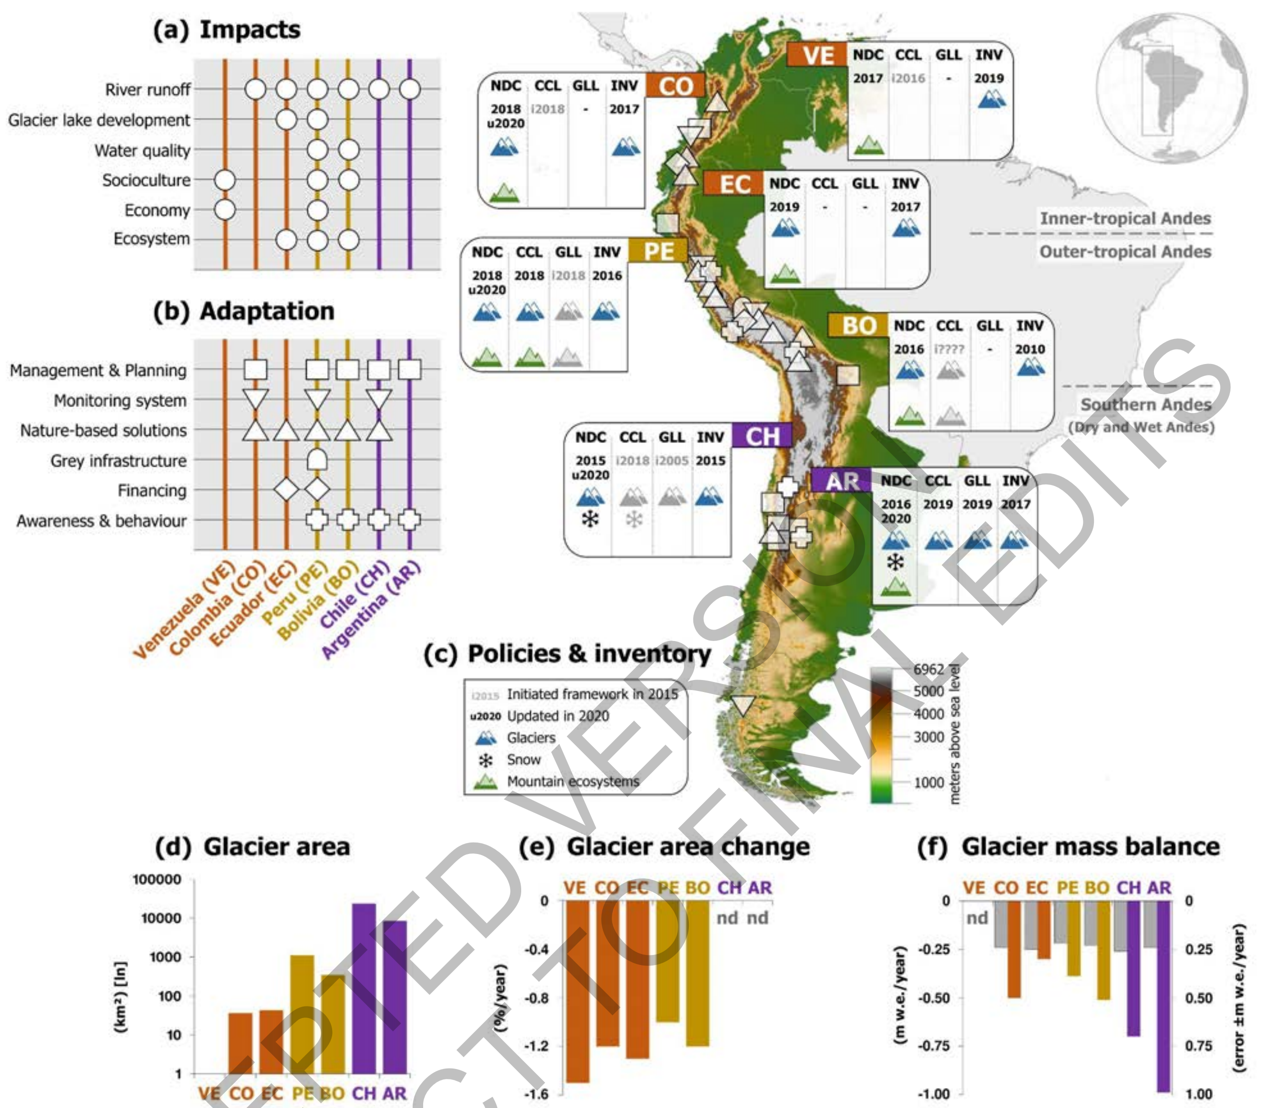

Figure 12.13: Overview map of observed glacier changes, associated impacts, adaptation and policy efforts across the Andes. (a) Selected impacts from glacier shrinkage. (b) Selected adaptation efforts (see upper-right map for the location of each adaptation measure), (c) Policies and glacier inventory: NDC = submission year(s) of Nationally Determined Contributions (u = update), CCL = climate change law, GLL = glacier law (i = initialized framework), INV = last national glacier inventory. The explicit mention of glaciers, snow and mountain ecosystems within each law/inventory is highlighted with the corresponding symbols (grey colour = not come into force). (d) Glacier area (km²) according to last national inventory. (e) Glacier area change (%/year) according to the baseline of the last national inventory. (f) Geodetic glacier mass balance (m w.e./year) and error estimate (±m w.e./year) retrieved from Dussaillant et al. (2019). nd = no data available. Further details can be found in the Appendix in Table SM12.6.

12.5.3.3 Policies, governance and financing

National policies on climate change, water protection, regulation and management laws are important focal areas of adaptation in the water sector (Section 4.7). Notable in the jurisdiction field is the Glacier Protection Law in place in Argentina (2010-2019), and under construction in Chile (since 2005). This first glacier law in the world represents a milestone for high-mountain conservation but is also criticized for hindering effective disaster risk adaptation measures and excluding local socioeconomic needs (Anacona et al., 2018). Furthermore, the first Framework Law on Climate Change was implemented in Peru (2018), and is underway in Colombia, Chile and Venezuela (Figure 12.13; Table SM12.6). Overarching regional institutions (e.g., OAS (2016)) and most countries in CSA promote a move towards more integrative and sustainable management of water resources through new legislations and financing mechanisms. For instance, new water laws including principles of Integrated Water Resources Management (IWRM) have entered into force, e.g., in Nicaragua (2007), Peru (2009), Ecuador (2014) and Costa Rica (2014) or are underway, such as in Colombia (since 2009). However, current realities in all regions show major challenges in implementing IWRM mechanisms and policies, related but not limited to political and institutional instabilities, governance structures, fragmented service provision, lack of economies of scale and scope, corruption and social conflicts (*high confidence*) (WWAP, 2020).

Many water-related conflicts in CSA are rooted in inequitable water governance that excludes water users from decisions on water allocation (*high confidence*) (Drenkhan et al., 2015; Vuille et al., 2018). In turn, inclusive water regimes leverage long-term adaptation planning. These have been addressed in some national strategies, such as in Brazil (Ministry of Environment of Brazil, 2016a). At the local level, a decentralized and participatory bottom-up water governance model was induced by civil society and research institutions to foster rainwater harvesting technologies reducing drought risk in semi-arid Brazil (NES) (Lindoso et al., 2018).

Water fund programs can generate important co-benefits for Sustainable Development contributing to improved governance and conservation of watershed systems in CSA. Nevertheless, only a few experiences have been evaluated as successful due to insufficient implementation, low decision-making of some stakeholder groups and poor evidence-based approaches (*medium confidence*) (Bremer et al., 2016; Leisher et al., 2019). Furthermore, financing mechanisms that produce incentives for sustainable water management have been promoted, tested or implemented. Payments for Ecosystem Services (PES) for water provision represent such an example and have been implemented across CSA since the 1990s (Grima et al., 2016).

Only about 50–70% of required financial resources are currently allocated per year to meet the national targets in the water, sanitation and hygiene (WASH) sector for the Sustainable Development Agenda (SDG 6) in several regions of CSA. This share drops down to less than 50% in NSA (Venezuela) and SES (Argentina, Uruguay, Paraguay), except for Panama in CA allocating more than 75% of required financial resources. For the implementation of NbS, evidence suggests that the overall expenditure remains well below 1% of total investment in water resources management infrastructure (WWAP, 2018). These funding deficits pose important limitations for future water provision, adaptation to changing water resources, and the achievement of the SDGs by 2030 (*high confidence*) (WHO, 2017).

12.5.3.4 Successful adaptation and limitations

Although a growing body of adaptation initiatives exists for CSA, evidence on effectiveness is scarce. In many parts of CSA the level of success of respective adaptation measures depends much on the governance of projects and stakeholder-based processes and is closely related to their effectiveness, efficiency, social equity and socio-political legitimacy (*high confidence*) (Adger et al., 2005; Rasmussen, 2016b; Moulton et al., 2021). Several Payments for Ecosystem Services experiences across CSA have been described as successful measures for watershed conservation and adaptation (*high confidence*). An example of success represents the Quito water fund in Ecuador which aims at improving the city's water quality by integrating public and private stakeholder interests with ecosystem conservation and local community development since the 2000's (Bremer et al., 2016; Grima et al., 2016) (case study 12.6.1). At the same time, in Moyobamba in Peru the development of a watershed protection program was leveraged by a multi-stakeholder platform process that enabled deep social learning (Lindsay, 2018). In turn, initiatives that do not consider the entire set of social-ecological dimensions and dynamics of adaptation or unintentionally increase vulnerabilities of human or natural systems, are at risk to lead to reduced outcomes (McDowell et al., 2021) or maladaptation (Reid et al., 2018; McDowell et al., 2019; Eriksen et al., 2021). However, systematic assessments of maladaptation in the water sector have barely been provided for CSA.

In CSA, only limited information on limits of adaptation in relation to water is available, for instance on possible path dependency of institutions and associated resistance to change (Barnett et al., 2015). Examples of soft adaptation limits (i.e., options to avoid intolerable risks currently not available) include the lack of trust and stakeholder flexibility, associated with unequal power relations that lead to reduced social learning, and poor outcomes for improved water management, as reported in e.g., NWS (Lindsay, 2018). An example for hard adaptation limits (i.e., intolerable risks cannot be avoided) in the region is the loss of livelihoods and cultural values associated with glacier shrinkage in NWS (Jurt et al., 2015).

Most barriers to advance adaptation in CSA correspond to soft limits associated with missing links of science-society-policy processes, institutional fragilities, pronounced hierarchies, unequal power relations and top-down water governance regimes (*high confidence*). One example is the abandonment of hydrological long-term monitoring sites within tropical Andean ecosystems (paramo) in Venezuela (Rodríguez-Morales et al., 2019) due to the lack of governmental support within a political crisis. In that regard, the collection and availability of consistent hydroclimatic and socioeconomic data at adequate scales represent an important challenge in CSA. Major adaptation barriers are furthermore reported from Central Chile in the context of a mega-drought since 2010, related to socioeconomic characteristics and a deficient bottom-up approach to public policy informing and development (Aldunce et al., 2017). These gaps could be bridged by strengthening transdisciplinary approaches at the science-policy interface (Lillo-Ortega et al., 2019) with blended bottom-up and top-down adaptation to include scientific knowledge with impact and scenario assessments into local adaptation agendas (Huggel et al., 2015b). For instance, a new allocation rule for the Laja reservoir in Southern Chile (SWS), based on consistent water balance modelling results, could inform policy and water management and potentially improve local water management and reduce water conflicts on the long term (Muñoz et al., 2019b).

12.5.4 Food, Fibre and other Ecosystem Products

The CSA region globally has the greatest agricultural land and water availability per capita. With 15% of the world's land area, it receives 29% of global precipitation and has 33% of globally available renewable resources (Flachsbarth et al., 2015). Agricultural commodities (coffee, bananas, sugar, soybean, corn, sugarcane, beef livestock) are some of the highest users of ecosystem resources such as land, water, nutrients and technology. These exports have gained importance in the past two decades as international trade and globalization of markets have shaped the global agri-food system. However continuous overuse on the environment might account for resource depletion (deforestation, land degradation, nutrient depletion, pollution), affecting the natural capital base. The effects of climate change on humans, via ecological systems, exacerbate the impact related to depletion of ecosystem services (Scholes, 2016; IPBES, 2018b; Castaneda Sanchez et al., 2019; Clerici et al., 2019; Tellman et al., 2020; Pacheco et al., 2021).

12.5.4.1 Challenges and opportunities

Even though there are large improvements in food availability in several regions, there is also a tendency of a decline in food self-sufficiency in many countries (Porkka et al., 2013; Rolando et al., 2017). Drought conditions in Central America and the Caribbean increased in line with climate model predictions (Herrera et al., 2018a). The direct social and economic consequences for the sector are evident in Central America's so-called Dry Corridor with a growing dependence on food imports (Porkka et al., 2013) and these degrees of dependency make the region more vulnerable to price variability, climatic conditions (Bren d'Amour et al., 2016; ECLAC, 2018) and therefore, to food insecurity if adaptation actions are not taken (*high confidence*) (Porkka et al., 2013; Bren d'Amour et al., 2016; López Feldman and Hernández Cortés, 2016; Eitzinger et al., 2017; Imbach et al., 2017; Lachaud et al., 2017; Harvey et al., 2018; Niles and Salerno, 2018; del Pozo et al., 2019; Alpízar et al., 2020; Anaya et al., 2020).

Given these circumstances, some regions in CSA (Andes region and Central America) will just meet, or fall below, the critical food supply/demand ratio for their population (Bacon et al., 2014; Barbier and Hochard, 2018b). Meanwhile, the more temperate part of South America in the south is projected to have agricultural production surplus (*low confidence*) (Webb et al., 2016; Prager et al., 2020). The challenge for this region will be to retain the ability to feed and adequately nourish its internal population as well as making an important contribution to the food supplies available to the rest of the world.

The access of agricultural products from the region to other markets might be conditioned on the adoption of low-carbon agriculture measures. Achieving net-zero emissions while improving standards of living is possible but requires developing transition policy frameworks to attain the target (Frank et al., 2019; Mahlknecht et al., 2020; Cárdenas et al., 2021).

12.5.4.2 Governance and barriers for adaptation

The governance of adaptation for CSA implies modifying agricultural, socio-economic and institutional systems in response to and in preparation for actual or expected impacts of climate variability and change, to reduce harmful effects and exploit beneficial opportunities (*high confidence*). CSA agriculture has a diversity of systems and segments of producers. While small-scale farmers have a big contribution to food production and food security, especially in developing economies, they face global policies oriented towards global commodity markets (Knapp, 2017; Fernández et al., 2019). Climate action initiatives that consider CSA's high levels of poverty and inequality to reduce these pervasive problems are central for adapting the region (Crumpler et al., 2020; Locatelli et al., 2020).

Since AR5, important advances at institutional level are observed based on the development and implementation of national adaptation plans for the agriculture and forestry sector among countries. Adapting to climate change entails the interaction of decision-makers, stakeholders, and institutions at different scales of government from the local to the national. The Climate-Adapted Sustainable Agriculture Strategy for the region of the Central American Integration System (EASAC) of the Central American Agricultural Council of Ministers of Agriculture, constitutes a valuable example of how undertake climate action in the agricultural sector, as a block of countries and in an intersectoral manner, to enhance results and make better use of resources (IICA, 2019).

In Brazil, the Low Carbon Agriculture program (Programa ABC) funds practices for reducing GHG emission in the sector (Government of Brazil, 2012), allocating about 15% of the total agriculture official finance portfolio, although it faces challenges to advance (Souza Piao et al., 2021). Costa Rica offers an example on how reforestation can help achieve Paris Agreement objectives. Reforestation through natural regeneration on abandoned pastures boosted forest cover from 48% in 2005 to 53.4% in 2010 (Reid et al., 2019; Cárdenas et al., 2021). Some key success factors included a strong institutional context, fiscal and financial incentives for reforestation, conservation measures such as payment for environmental services, cattle ranch subsidy reform, and a historically strong enforcement and focus on land titles that favoured the restoration of lands. Uruguay offers another example, with the farm sector contribution of 32.8% of all exports and 73.8% of the country's emissions, so decarbonisation is not just an environmental issue but an economic competitiveness one as well. In the INDCs submitted to the UNFCCC in 2015, Uruguay set a specific target for the agriculture sector to reduce enteric methane emissions intensity per kilogram of beef (live-weight) by 33% to 46% in 2030 through improving efficiency of beef production by controlling the grazing intensity to increase animal intake, reproductive efficiency, and daily weight gain (Picasso et al., 2014).

It is relevant to generate conditions for the development of sustainable agricultural practices in a frame where factors associated with climate have become important for producers, given recent experiences of drought and lack of water (*high confidence*) (Clarvis and Allan, 2014; Roco et al., 2016; Hurlbert and Gupta, 2017; Pérez-Escamilla et al., 2017; Cruz et al., 2018; Zúñiga et al., 2021). Solutions that consider relevant drivers that have demonstrated positive effect in diffusion of adaptation strategies are more efficient (Table 12.8). Some conditions such as the promotion of education programs; participation in cooperatives; credit access; land tenure security can help in this task. In the same line, in CSA some elements such as technology and information access, and local knowledge, reinforce climate change adaptation (Khatri-Chhetri et al., 2019; Piggott-McKellar et al., 2019). As is stated in Table 12.8 barriers of different origin persist for climate change adaptation in the region increasing vulnerability of farming systems and rural livelihoods.

Limited information regarding cost-benefit analyses of adaptation is available in the region as well as avoiding maladaptation effects and promoting site-specific and dynamic adaptation options considering available technologies (*medium confidence*) (Roco et al., 2017; Zavaleta et al., 2018; Ponce, 2020; Shapiro-Garza et al., 2020).

Climate Information Services has an important role in climate change adaptation and there is a recognized gap between climate science and farmers (*high confidence*) (Vaughan et al., 2017; Loboguerrero et al., 2018; Tall et al., 2018; Thornton et al., 2018; Ewbank et al., 2019). Such services should address the challenges of ensuring that climate information and advisory services are relevant to the decisions of small-holder and family farmers, providing timely climate services access to remote rural communities with marginal infrastructure and ensuring that farmers own climate services and shape their design and delivery. An interesting case facing this gap is the implementation of local technical agro-climatic committees in Colombia which allow to share and to validate climatic and weather forecasts; and crop model results to seasonal drought events (Loboguerrero et al., 2018). Another example is the web service, AdaptaBrasil-MCTI, forecasting the risk of climate change impact on strategic sectors (e.g., food, energy, water) in Brazil (Government of Brazil and Ministry of Science Technology and Innovation Secretariat of Policies and Programs, 2021).

Barriers to financial access are present in the region restricting effective adaptation to extreme weather events (*high confidence*) (Chen et al., 2018; Fisher et al., 2019; Piggott-McKellar et al., 2019; Vidal Merino et al., 2019; de Souza Filho et al., 2021). In 2014, the penetration rate of this type of insurance in the region averaged 0.03% of GDP, and a few countries dominate the market (Brazil, Argentina). Beyond these three countries, some initiatives also exist in Uruguay, Paraguay, Chile and Ecuador. In most Latin American and Caribbean countries, the public sector plays an important role in providing insurance or reinsurance and coexists with private sector companies (Cárdenas et al., 2021). Insurance protections represent a strategy to transfer climate risk to protect the wellbeing of vulnerable small farmers and accelerate uptake (recovery) after a climate-related extreme weather event. Lack of finance and proper infrastructure is compounded by limited knowledge of sustainable farming practices and high rates of financial illiteracy (*high confidence*) (Hurlbert and Gupta, 2017; Piggott-McKellar et al., 2019).

Insufficient access to digital services and technologies further widens the gap between the rural poor and more urban populations of Latin America and the Caribbean (*medium confidence: insufficient evidence, high agreement*). In turn, these factors compromise productivity and competitiveness. Support for this group can be focused on both economic competitiveness and social development. Finally, to align identified adaptation options as a priority for achieving future food security in the NDCs of CSA countries to mitigation commitments, it will be essential to highlight synergies by generating evidence (national research) in relation to progress towards increasing productivity, resilience and reducing GHG; and also demonstrating its added value as a development initiative (Rudel et al., 2015 sustainable; Loboguerrero et al., 2019).

12.5.4.3 Adaptation options

In order to contextualize the adaptation options at the regional level, the majority of the NDC of the CSA countries reported the observed and/or projected climate-related hazards: occurrence of droughts and floods (80% of countries each), followed by storms (45%) and landslides (30%), as well as extreme heat, wildfire and invasion by pests and non-native species in agriculture (25% each) (Crumpler et al., 2020).

Main adaptation options for climate change in the region include preventive measures against soil erosion; climate-smart agriculture which provide a framework for synergies between adaptation, mitigation and improved food security; climate information systems; land use planning; shifting plantations in high altitude to avoid temperature increases and plagues; improved varieties of pastures and cattle (Lee et al., 2014; Jat et al., 2016; Crumpler et al., 2020; Moreno et al., 2020a; Aragón et al., 2021). Agricultural technologies are not necessarily changing, but the economic activity is shifting to accommodate increasing climate variation and adapt to changes in water availability and ideal growing conditions (*high confidence*) as is observed in Argentina, Colombia and Brazil (McMartin et al., 2018; Rolla et al., 2018; Sloat et al., 2020; Gori Maia et al., 2021). Coffee plantations are moving further up mountain regions with the land at lower elevations converted for other uses. In Brazil, crop modelling suggests the need for the development of new cultivars, with a longer crop cycle and with higher tolerance to high temperatures, a necessary technological advance for maize, an essential staple crop, to be produced in the future. Additionally, irrigation becomes essential for sustaining productivity in adverse climate change scenarios in several regions of CSA (McMartin et al., 2018; Lyons, 2019; Reay, 2019).

Livestock production is for small farmers one of the main sources of protein and contributes to food security (Rodríguez et al., 2016). The importance of this sub-sector in CSA, will continue to increase as the demand for meat products does as well in the coming years, driven by growing incomes in the region (OECD and FAO, 2019). However, the increase in animal production has been associated with land degradation, triggered by the conversion of native vegetation to pastureland and aggravated by overgrazing and abandoning of the degraded pastures (Baumann et al., 2017; ECLAC, 2018; Müller-Hansen et al., 2019). Sá et al. (2017) simulated the adoption of agricultural systems based on Low-Carbon Agriculture (LCA) strategies towards 2050. According to the simulation, the adoption of LCA strategies in the SA region can alter the growing trend of Land Use and Land Use Change emissions and at the same time, it can increase meat production by 55Mt for the entire period (2016–2050). The restoration of degraded pasture and livestock intensification account for 71.2%, and integrated crop-livestock-forestry system contributes 28.8% of total meat production for the entire period. These results indicate that combined actions in agricultural management systems in SA, can result in synergistic responses that can be used to make agriculture and livestock production an important part of the solution of global climate change and advance food security (*medium confidence: insufficient evidence and high agreement*) (Zu Ermgassen et al., 2018; Pompeu et al., 2021). Crop-Livestock-Forestry-Systems are also important for climate change adaptation as they provide multiple benefits, including the coproduction of food, animal feed, organic fertilizers and soil organic carbon sequestration (Sharma et al., 2016; Rodríguez et al., 2021), achieving mitigation and adaptation goals (*high confidence*) (Picasso et al., 2014; Modernel et al., 2016; Modernel et al., 2019; Rolla et al., 2019; Locatelli et al., 2020). A recent analysis of agroforestry in Brazil, has shown positive and relevant impacts on the heads/pasture area rate in livestock production and that the system may have also stimulated a shift toward other production activities with higher gross added value (Gori Maia et al., 2021). Agroforestry has also proven to have protective benefits to obtain more stable, less fluctuating yields due to climate damages in coffee production (*high confidence*) (Bacon et al., 2017; Durand-Bessart et al., 2020; Ovalle-Rivera et al., 2020). In the same way, the production of plant-based fibre can be less vulnerable to economic and climatic variability through farming systems diversification. Textile fibre crops for the case of cotton include crop rotation, agroecological intercropping and agroforestry (Oliveira Duarte et al., 2019).

Adaptation strategies also concern Indigenous agriculture, i.e., the vast majority of the 44 million Amerindians (CEPAL, 2014). Indigenous knowledge and local knowledge (IK and LK) can play an important role in adaptation (Zavaleta et al., 2018). On one hand, they preserve the conservation of a very rich agrobiodiversity that is likely to meet the challenges of climate change (*high confidence*) (Carneiro da Cunha and Morim de Lima, 2017; Magni, 2017; Emperaire, 2018; Donatti et al., 2019) and on the other hand, the sustainability of large territories that assure their livelihood (Singh and Singh, 2017; Mustonen et al., 2021). In the Andes, ancient technologies increased the quantity of crops produced and allowed for coping with climatic changes and water scarcity, while nutrition conditions were improved (*high confidence*) (López Feldman and Hernández Cortés, 2016; Parraguez-Vergara et al., 2018; Carrasco-Torrontegui et al., 2020 food). Also, fire prevention management, protection against forest and biodiversity loss, are recognized as important elements in Indigenous knowledge (Mistry et al., 2016; Bowman et al., 2021).

Table 12.8: Recent studies related to climate change adaptation of agricultural systems and its determinants in the CSA Region.

Authors, year	Countries	Sample size (n)	Approach of the study	Crop systems	Adaptation strategies	Main drivers promoting climate change adaptation	Main barriers limiting climate change adaptation	Main barriers detected
de Souza Filho et al. (2021)	Brazil	175	Quant.	Cattle farmers	Integrated crop-livestock and livestock-forestry systems	Credit access Extension services	Lack of resources	Lack of agricultural market access strategies
Magalhães et al. (2021)	Brazil	94	Qual.	Several crops	Farm management	Previous experience with risks	Inadequate infrastructure Low purchasing power	Infrastructure limiting opportunities
Carrer et al. (2020)	Brazil	175	Quant.	Several crops	Agricultural insurance	Schooling	Higher risk propensity	Limited financial

						Technical assistance		market access
Quiroga et al. (2020)	Nicaragua	212	Quant.	Coffee	Several adaptation measures	Farm size Awareness of climate change Schooling	Limited access to rain-water	Absence of climate change education
Bro et al. (2019)	Nicaragua	236	Quant.	Coffee	Crop Soil and water	Schooling Participation in cooperatives Radio	Household size	Institutional framework to promote cooperatives

12.5.5 Cities, Settlements and Infrastructure

CSA is the second most urbanized region of the world, with 5 megacities and half of urban population in 129 secondary cities (UNDESA, 2019), huge metropolitan areas concentrated on the coast and an increasing number of small cities by the sea (Barragán and de Andrés, 2016). Besides the many climatic events threatening urban areas in the region (extreme heat, droughts, heavy storms, floods, landslides), cities by the coast are also exposed to sea level rise (SLR) (Section 12.3; Figure 12.6; Dawson et al., 2018; Leal Filho et al., 2018; Le, 2020). Main determinants of urban vulnerability assessed in the region are poor and unevenly distributed infrastructure, housing deficits, poverty, informality and the occupation of risk areas, including low elevation coastal zones (Section 12.3). Those features of urban systems increase the risks to health, ecosystems and its services, water, food and energy supply (Section 12.4). Impacts of climate events on urban water supply, drainage and sewer infrastructures are the most reported in the region (Section 12.3; Figure 12.9).

12.5.5.1 Challenges and opportunities
